Six Dishes of Ripe Dessert Fruit.—Lord Hillingdon (gr. Mr. J. Skelton), Sevenoaks, won the 1st prize with fruits of tempting appearance. The principal dishes were of Muscat of Alexandria Grapes, Lady Palmerston Peach, and Cox's Orange Pippin Apple; 2nd, the Duke of Wellington (gr. Mr. E. Matthews, Strathfieldsaye, who had excellent bunches of Mrs. Pearson Grapes; 3rd, G. Miller, Esq. (gr. Mr. J. Keddie), Academics, Bushey, Herts.

Grapes.

The Grapes in all the classes were especially good. Although the bunches were not of sensational size they were beyond the average of good types in shape, and sufficiently furnished with large, well-coloured berries. The varieties Black Hamburgh and Muscat of Alexandria were exceptionally well finished. There were 6 exhibits of 3 varieties, 2 bunches of each, and G. Miller, Esq., excelled easily. His varieties included magnificent bunches of Alnwick Seedling, Appley Towers, and Madresfield Court (black), and Lady Hutt and Muscat of Alexandria (white); 2nd, the Duke of Newcastle, who showed splendid Gros Colmar and Chasselas Napoleon; 3rd, C. A. Cain, Esq.

Four Varieties, 2 bunches of each.—Lord Hillingdon, who included almost perfect Muscat's and Mrs. Pearson, was the only exhibitor and was awarded the 1st prize. He also won the 1st prize for 2 bunches of Black Hamburgh, with magnificent examples.

Lord Hillingdon was also 1st for Mrs. Pince variety, and 2nd with Madresfield Court, and in the class for any other black Grape. The Duke of Newcastle won 1st prizes for Madresfield Court, with Muscat Hamburgh for any other black Grape, for any other white Grape with Mrs. Pearson, and was 2nd in the strong Muscat of Alexandria class, and for Mrs. Pince.

Mrs. W. Rudall (gr. Mr. H. H. Brown), Castle Hill, Englefield Green, was 1st for Black Alicante; 2nd, the Duke of Wellington, W. H. Nockolds, Esq. (gr. Mr. F. W. Herbert), Nutfield Court, Redhill, was 1st for Prince of Wales, and Mr. Jas. Lock excelled with exceptional bunches in the class for Muscat of Alexandria.

Collection of Hardy Fruit.

Mr. R. Steward, Painshanger Gardens, Hertford, was the only exhibitor, but he staged a very representative collection of excellent fruits, and deservedly received the 1st prize. Besides splendid Apples such as Rival, Chas. Ross, Mère de Ménage, Middle Green, and Emperor Alexander, he showed dishes of Hailshamberry, Painshanger Red Currant, Figs and Melons. Of the Pears Brockworth Park, Glou Morceau, Marguerite Marrillat and Durondeau were very fine.

Nurserymen's Classes.

Messrs. H. Cannell and Sons were 1st in the premier nurserymen's class. The arrangement was exceedingly attractive, and the exhibit was composed of high-class fruits equal in quality to any we have seen. Apples predominated, and these were of beautiful colour, good form, and useful, even size. The highest colour was seen on Worcester Pearmain, Baumann's Red Reinette, Emperor Alexander, King of the Pippins, Gascoyne's Scarlet, Calville Rouge, Précoce, Rival, Charles Ross, and Duchess's Favourite. Of less showy appearance, but none the less valuable, were Lane's Prince Albert, Lord Derby, Autumn Pearmain, Warner's King, Norfolk Beaufin, and Bramley's Seedling, though for size and general excellence none was better than the central stand of Peasgood's Nonsuch. Boxes of most brilliant Dartmouth Crab were most attractive; 2nd, Messrs. W. Seabrook and Sons, Ltd., who staged excellent King of the Pippins, Worcester Pearmain, Cox's Orange Pippin, Gascoyne's Scarlet, Bismarck, Melon, and Allington Pippin amongst their many excellent Apples, and Fertility and Beurré Clairgeau Pears.

In the smaller class for fruits staged on a 20-feet run by 6 feet tabling the competition was closer; Mr. H. Clost won the 1st prize. The Apples in his collection were particularly good—well coloured and of good, useful sizes. Perhaps the best of the dessert varieties were Worcester Pearmain, Cox's Orange Pippin, Calville Rouge, Précoce, Duchess' Favourite, and Allington Pippin, while of the kitchen sorts Peasgood's Nonsuch, Bramley's Seedling, Emperor Alexander and Newton Wonder were the best. Pears were represented by a dish of Jamieuse Pitmaston Duchess; 2nd, Messrs. H. Spooner and Sons, whose Apples were characterised by much golden sheen and fine general appearance; 3rd, Messrs. James Nash and Sons.

The 20 baskets of cooking and dessert Apples were especially finely coloured and of good appearance. The 1st prize was won by Col. J. F. Honeyball (gr. Mr. G. F. Packman), and his outstanding baskets were of Chas. Ross, Allington Pippin, Paroquet, Coronation, Mère de Ménage, Bramley's Seedling, Peasgood's Nonsuch, and Cheltenford Wonder; 2nd, Lt.-Col. H. L. Weir, Ham Green, Kent, who staged smaller, but very good examples.

Gardeners' and Amateurs' Classes.

The collections of 24 dishes of Apples, 16 of kitchen and 8 of dessert varieties, made an interesting show. J. Liddell, Esq. (gr. Mr. R. Learmouth), Sherfield Manor, Basingstoke, was 1st. He included King of Tompkins' County, Allington Pippin, Chas. Ross, and Ribston Pippin (dessert); Blenheim Pippin, Bramley's Seedling, Peasgood's Nonsuch, Lane's Prince Albert, Gloria Mundi and Mère de Ménage (cooking); 2nd, Mr. R. Steward.

C. A. Cain, Esq., won 1st prize for 6 dishes of cooking Apples Lane's Prince Albert, The Queen, and Peasgood's Nonsuch in magnificent condition, and with equally high-class Rival, Chas. Ross, Allington Pippin, and Washington, and was also 1st for 6 dishes of dessert Apples. With quite the finest Pears in the show the same exhibitor won the 1st prize for 9 dishes of dessert Pears; 2nd, John Liddell, Esq.

C. H. Berners, Esq., was 1st for Plums, with splendid Coe's Violet, and Damsons. Mr. F. G. Gerrish, Pend'ley Manor Gardens, Tring, showed the best Morello Cherries, and with splendid Queen Alexandra, Autumn Raspberries. F. E. Palmer, Esq. (gr. Mr. H. E. Wallis), Sherfield-on-Loddon, won the 1st prize for Raspberries.

County Classes.

There was a great falling off in exhibitors in these classes, which are restricted to the various groups of county districts. 1st prizes were won by Major Hennessy (gr. Mr. J. Hygate), Tubney Hall, Winchfield, for Apples in the Kent Class; John Cope, Esq., Ferndale, Teignmouth, for Apples in Class 29; Sir Ed. Pearson (gr. Mr. W. Stedman), Brickendonbury, Herts, for Apples and Pears in Class 30; Sir Montagu Turner (gr. Mr. A. Barrett), Bedfords, Romford, for Apples in Class 31; C. H. Berners, Esq. (gr. Mr. W. Messenger), Wolverstone Park, Ipswich, for Pears in Class 31; A. Wood, Esq., Woodwell House, Carnforth, for Apples in Class 34; Capt. C. L. Gordon (gr. Mr. Jas. Duff), Castle Douglas, Kirkcudbright, for Apples in Class 35, and the Earl of Bessborough (gr. Mr. T. Tomalin), Piltown, Co. Kilkenny, for Apples grown in Ireland.

SINGLE-DISH CLASSES.

Dessert Apples.—Except for the two classes for any varieties not named, which require 8 fruits, these classes called for 6 fruits to a dish. In several classes there were either no exhibits or the specimens were not considered worthy of a prize, but in the majority of instances the quality and number of exhibits were very good.

1st prizes were won by J. B. FORTESCUE, Esq., for Mr. C. Page), Dropmore, Bucks, for (a) Adams' Pearmain, (b) Egremont Russet, and (c) Cox's Orange Pippin; Sir EDWARD PEARSON, for Allington Pippin; W. H. NICHOLLS, Esq., for American Mother; the Duke of WELLINGTON, for Bismarck Pippin; the Earl of BESSBOROUGH, for (a) Lord Hindlip and (b) Wealthy; E. E. PALMER, Esq., for Charles Ross, and with Jefferson for any other variety of early Apple; in the class J. B. FORTESCUE, Esq., was 2nd with Economic Orange; Major HENNESSY, for Ribston Pippin, Rival, and W.A. King of Tompkins County for any other variety of late Apples in which class the Duke of WELLINGTON was 2nd with Court Pendu Plat; G. MALSH, Esq., Marchmont, Warrington, for Cox's Orange Pippin, and St. Edmund's Pippin; Mr. J. TUPP, Bear Wood Gardens, Wokingham, for Cox's Orange Pippin; J. COPE, Esq., for James Grieve and Margil.

Cooking Apples.—The 1st prizewinners were Sir MONTAGU TURNER, for Bismarck and Dumelow's Seedling; Major HENNESSY, for (a) Bloenheim Pippin, (b) Bramley's Seedling, (c) Mère de Ménage, (d) Peasgood's Nonsuch, (e) The Queen, and (f) Lane's Prince Albert; the Earl of BESSBOROUGH, for (a) Lord Derby, (b) Grenadier, (c) Lane's Prince Albert, and (d) any other variety; J. WARNER'S King, G. MARSH, Esq., for a Stirling Castle and (b) any other variety, with Charles Ross, in which class the Earl of BESSBOROUGH was 2nd with Loddington; R. COLLARD, Esq., Knaresley, Shotfield, for Ecklinville; Mr. J. TUPP, for Gold in Noble and Edward VII., and the Duke of WELLINGTON for Grenadier, Lane's Prince Albert, and Newton Wonder, and Sir EDWARD PEARSON for Emperor Alexander.

Dessert Pears.—H. BERNERS, Esq., for 1st prizes for (a) Beurré Rose, (b) Beurré Hardy, (c) Beurré Superfin, (d) Charles Ernest, (e) Doyenné du Comice, (f) Easter Beurré, (g) Princesse Dagmar, and (h) with Marie Benoist for any other late variety, in which class C. H. COOKE, Esq., was 2nd with Beurré Bachelier; Sir M. THOMAS, for Fondante d'Automne; C. H. COMBE, Esq., for Mr. G. A. Kemble, Cobham Park Succès, for Louise Bonne of Jersey, and the Duke of NEWCASTLE for Clapp's; J. B. FORTESCUE, Esq., for Beurré d'Anjou; H. SHIELD, Esq., Cobham Surrey, for Conference, and the Duke of WELLINGTON for Doyenné du Comice.

AFFILIATED SOCIETIES CHALLENGE CUP CLASS.

The only exhibit in this class, which required 6 dishes each of dessert Apples, cooking Apples and dessert Pears, was from the KNEBWORTH AND DISTRICT HORTICULTURAL SOCIETY, Hertfordshire, and it was awarded the Challenge Cup. The exhibit was a highly creditable one and included Dumelow's Seedling, and Bramley's Seedling amongst the Cookers, and Beurré Hardy amongst the Pears, and Pomeroy, King of the Pippins, Rival, The Queen, and Lane's Prince Albert amongst the Apples.

Dahlia Committee.

Present: Messrs. John Green (in the chair), A. Turner, E. H. Jenkins, D. B. Crane, J. A. Barrett, H. J. Jones and Chas. H. Curtis.

About three dozen new Dahlias were submitted for the jurisdiction of this joint committee and the following novelties gained the Royal Horticultural Society's Award of Merit and the National Dahlia Society's First-class Certificate:

Hebe.—A large, single, decorative variety, broad-petalled and stiff-stemmed. The colour is light mauve, with a narrow yellow zone around the golden centre.

Standard.—An attractive, large-flowered, decorative Dahlia closely approximating to the Cactus type in form. Very double, and with strong, stiff stems. Colour bright rosy mauve. These two varieties were shown by Messrs. J. STRED WICK AND SON.

Nooch Bill.—An extremely beautiful medium-sized decorative variety that for colour and freedom of flowering should find many admirers. For garden decoration it should prove very popular. The bloom has three rows of florets and is flame-coloured, shading to rose-pink at the tips of the florets, and with a golden centre.

Ino.—A full-sized Collerette variety of good shape and with a large ring of cobalt segments. The colour is yellow, with a heavy overwash of pink towards the ends of the florets. Cobalt light yellow; stems strong and stiff.

Confidence.—A charming medium-sized, Pæony-flowered variety, free-flowering and elegant. The colour is a delightful shade of pink flushed over blush, and with a little yellow shading passing into the base of the florets from the yellow centre.

Queen.—A very large semi-double Pæony flowered Dahlia with florets nearly 2 inches broad. The colour is rich scarlet with a suspicion of orange underlying the scarlet-golden centre.

Flower.—Another giant decorative Dahlia brought by Souvenir de G. Dragon group, and measuring 10 inches in diameter. The blooms are double, shapely, and borne on good stems. The colour is intense dark maroon with a bluish centre. The foregoing five varieties were exhibited by Messrs. BARRELL AND CO.

Vesuvio.—A distinct decorative Dahlia of fairly large size. The florets have interlocking petals giving them a somewhat flatted appearance so that the build of the flower is unusual. The colour is light rose-pink. Shown by Mr. J. A. BARRELL, Anerley.

Lord.—One of the Star Dahlias. Very free flowering, with neat, bright pink, yellow-centred flowers, borne on stiff, dark stems. A very showy variety. Shown by Mr. CHAS. TURNER.

SCOTTISH HORTICULTURAL.

OCTOBER 1.—The monthly meeting of this Association was held at 5, St. Andrew Square, Edinburgh, on this date, Mr. Robert Fife, president, in the chair.

A lecture was delivered by Mr. J. S. Cuthbertson on bee-keeping in bee-culture at the Edinburgh and East of Scotland College of Agriculture, on "The Year and its Critical Periods." Mr. Cuthbertson stated that the increasing attention which had been devoted to bee-keeping in this country was due to the fact that it was a hobby that could be carried on at home at very little cost, and to the possible extension of bee-keeping as a profitable industry. The enormous quantity of fruit imported showed very clearly the great possibilities of production. Fruit could be grown with more readily available land if it could be proved to be suitable for bees, and increased transport facilities might in many cases be profitably provided at home. The questions of availability of food and transport for bees were being overdone and ought to be considered in view of the war conditions of reconstruction.

There was no doubt that the Arran could be successfully and profitably grown in Scotland when attention was paid to the best breeds, pedigree stock and longevity, it required an elevated situation, a rich loam, a plentiful rainfall, good drainage, and abundant sunlight. But although these might be considered to be ideal conditions they were by no means indispensable, and, under proper treatment, the Apple grew and fruited well under widely different environments. As regards stocks, Mr. Chisholm strongly recommended the planting of bush trees grafted on the broad-leaved Paradise, on account of their coming earlier into bearing, their greater productiveness, and their being better under control for carrying out the various cultural operations. He pointed out that, whether the planting was done in autumn or spring, plants should be ordered early, and that they should be lifted from the nursery lines in autumn and "heeled" into a trench till they were required. The principle was laid down that pruning and manuring should go hand in hand, instead of the all too prevalent practice of pruning ostensibly for the production of fruit and at the same time applying manures in such ill-balanced proportions as to produce annually a great amount of useless wood. He deprecated the large number of varieties on the market, and he maintained that the inferior sorts should be ruthlessly weeded out. In selecting varieties soil was the dominating factor for or against success of any particular one, but many sorts succeeded well on any reasonably good soil, whether light or heavy. For this purpose the following selection was given:—Dessert: Beauty of Bath, Gladstone, James Grieve, Worcester Pearmain, Irish Peach, Allington Pippin; Culinary: Golden Spire, Lord Grosvenor, Early Victoria, Bismarck, Lane's Prince Albert, Bramley's Seedling.

The exhibits were: Collection of Apples from Mr. CHISHOLM (silver medal); collection of Apples from Messrs. STORRIE AND STORRIE, Glenalmond (silver medal); collection of Apples and Pears from J. W. COWAN, Esq., Dalhousie Castle (bronze); Mr. W. CRIGHTON (silver medal); collection of Apples, Pears, etc., from Mr. J. E. DAVIS, Bickwood Hall Gardens, Sheffield (silver medal); collection of vegetables from City of Edinburgh Parks Department, per Mr. McHattie (silver medal); Apple Bathe Neilson, from Mr. J. W. SCARLETT, Scunthorpe; fruits of broad-leaved Paradise Apple from Mr. W. LAMONT, Edinburgh; Decorative Dahlias from Messrs. DOBBIE AND CO., Edinburgh (Decoratives Dobbie's Bolden, Dazzler, Sparkler, Ruby Gem and Vindictive, and Collerette Hussar, were awarded First-class Certificates).

ROYAL SCOTTISH ARBORICULTURAL.

SEPTEMBER 28.—At a meeting of the Council of this Society, held at 19, Castle Street, Edinburgh, on this date, over two hundred new members were elected as a result of a special appeal sent out by the president, the Duke of Buccleuch, K.T. The following resolution was unanimously adopted by the meeting:—"The Council of the Royal Scottish Arboricultural Society welcomes the gratifying announcement made by Viscount Peel in the House of Lords on August 8 in reply to the Earl of Selborne that the report of the Forestry Sub-Committee of the Reconstruction Committee has been accepted by the Government and that a Central Authority for Forestry for the United Kingdom would be set up and the policy of planting would be pursued with the least possible delay. The Council trusts that the Government's intentions so announced will receive legislative sanction as soon as Parliament reassembles. The Council respectfully repeats to the Government the request that this Society should have an opportunity of considering and expressing its views upon schemes in contemplation for Scotland before they are actually adopted."

NATIONAL CHRYSANTHEMUM.

OCTOBER 7.—The Floral Committee of this society met at Essex Hall, Strand, W.C., at 2.30 p.m. on this date. No new variety was submitted for award and the meeting was a very brief one. Several interesting matters relative to the future work of the Committee were discussed informally, and the opinion was expressed that the Chrysanthemum known variously as Cindella and Sunchty is the best early white market sort.

TRADE NOTES.

NEW PRICES FOR ONIONS.

An Order has been issued establishing maximum prices for British eating and pickling Onions of the 1918 crop, and comes into operation on the 14th inst. Eating Onions are defined as those which will not pass through a sieve of 1-inch mesh, and pickling Onions as those which will go through the riddle. It is provided that Onions must be sold by weight, and eating Onions must not be used for making pickles. The maximum prices are as follows:

EATING ONIONS.

Time of delivery.	Growers' maximum price, f.o.r. on rail per cwt.	Sales of 1 cwt. or more, per cwt.	Retail Prices. Sales of 1 stone or more, but less than 1 cwt.	Sales of less than 1 stone per lb.
1918	s. d.	s. d.	s. d.	d.
Before and on Oct. 31	25	34 0	1 5	4½
Nov. 1 to Nov. 30 ..	29	35 0	1 6	4½
Dec. 1 to Dec. 31 ..	20	26 0	1 3	3½
1919				
Jan. 1 to Jan. 31 ..	22	28 0	1 11	5
Feb. 1 to Feb. 28 ..	34	40 0	2 2	5½
Mar. 1 to Mar. 31 ..	36	42 0	2 5	5½
April 1 and after ..	38	44 0	2 8	6½

PICKLING ONIONS.

Any time	30	36 0	1 8	4½

The Order makes it an offence to sell British Onions mixed with any other Onions, or falsely to represent or misdescribe British Onions as imported Onions, or imported Onions as British Onions. In the case of Onions not separated when sold by the growers, these, if sold for delivery before December 31, must be sold at prices applicable to eating Onions, and if sold after December 31, at prices applicable to pickling Onions. The maximum wholesale dealer's profit is 35s. per ton, and if the Onions pass through the hands of more than one wholesale dealer this profit must be shared.

Growers who carry on separate businesses as wholesale dealers may apply to the Director of Vegetable Supplies, 100, Cromwell Road, London, S.W. 7, for licences to sell their own Onions as wholesale dealers. Onions may be sold by retail only by registered retail dealers in eating Potatos, or by growers whose total Onion crop is not more than 10 cwt. Retail dealers may charge 4d. a lb., with a maximum of 2d., for delivery to customers. The Order does not apply to Shallots, Potato Onions, or to Onion sets sold for planting. All contracts are cancelled, except in respect of deliveries before October 7.

MESSRS. DOBBIE AND CO., Edinburgh, have appointed Mr. Harry Wright manager of their Marks Tey establishment. Mr Wright was Mr Ireland's chief assistant, and has been in the service of the firm for over 22 years.

CROPS AND STOCK ON THE HOME FARM.

FARM ORCHARDS.

IT is well known that the majority of farm orchards are ill attended. The trees are planted, or rather they are "stuck in," and attention ends there. This is a short-sighted policy. At Swanmore we have 6 acres of Apple trees, bushes and standards, which succeed well; the trees are profitable, interesting, and their crops of value to the community.

I should not advise the farmer with but little knowledge of fruit-growing to plant bush trees, but standards, with 3 feet stems if possible, so that the orchard may be used for grazing sheep, calves or pigs. When trees of this type are established they require less attention than bushes, and that is important to the farmer with a limited knowledge of fruit growing. Where Pear trees succeed I advise the inclusion of a few Pear trees of desirable varieties. In the case of all kinds of fruit I would limit the number of varieties to a minimum. Plums should be more extensively planted, and good varieties should be selected. Such sorts as the Michaelmas Plum, which is really a Bullace, are unprofitable, and one may surmise what Monarch Plums would realise if they were planted instead.

A farm orchard on grass may be utilised for other purposes, and if possible it should be near the homestead, as being handier for young cattle. The best site is one with a southern aspect, or a westerly one would suffice. Shelter from the east and north should be provided, not only for the trees but for the cattle.

No other kind of shelter or fence is so good as a Quick hedge. Austrian Pines, intermixed with Larch and Black Italian Poplars, would form the quickest growing screen.

Standard trees of all kinds of fruits should be not closer than 24 feet apart, and in some cases 30 feet is better. The former distance will suffice if space is not unlimited.

The following varieties are suitable:—

Apples—Culinary: Grenadier (August), Norfolk Beauty (September), Royal Jubilee (October), Bramley's Seedling (November, December and January), with Dumelow's Seedling (Wellington) to follow.

Dessert. Devonshire Quarrenden (August), Worcester Pearmain (September), James Grieve (October), Blenheim Pippin (November), Cox's Orange Pippin (December), with King of Tompkins' County and King's Acre Pippin to follow.

Pears—Williams' Bon Chrétien (September), Louise Bonne of Jersey (October), Doyenné du Comice (November), with Pitmaston Duchess for stewing.

Plums. Rivers' Early Prolific (August), Czar, Victoria, Jefferson, Washington, and Pond's Seedling (September), with Monarch for later use. If Damsons are required choose the Merryweather and Langley Bullace.

The main causes of all success with fruits are (1) improper preparation of the ground before planting, (2) neglect or a want of knowledge in pruning, (3) neglect of spraying the trees. The first of the three causes is the only one that concerns the intending planter just now. Especially for stiff soil is a thorough preparation of the ground an absolute necessity to success. A station at least 4 feet square and not less than 2 feet deep should be prepared by trenching, or, better, throwing out the whole of the soil, separating the turf, the surface soil, and the subsoil. Many persons put the turf at the bottom of the hole, whereas it is needed on the surface in which to plant the trees. The subsoil below 2 feet should be broken up another foot deep and left at the bottom. Half-decayed farmyard manure should be liberally added to the surface soil to encourage vigorous growth, the aim being to obtain a large area of branch growth in the shortest possible time, because without this a large fruit crop cannot be obtained. Many writers err in advising that animal manure should not be employed at planting time. In all cases plant the trees on the surface in newly trenched soil, covering the roots with a slight mound. With the gradual sinking of the trenched soil the trees will eventually settle down to the normal level, whereas if planted 6 inches below the natural surface the roots would eventually be much too deep, which is the main cause of canker. Directly the trees are planted they should be staked firmly to prevent the wind swaying them to and fro, as this would cause the roots to become damaged and loosened in the soil. The stakes should be not closer than 6 inches from the stems, to obviate bruising the bark. If cattle are turned into the orchard the stems should be protected. Three stakes, at least 6 feet high, should be driven into the soil 1 foot from the stems and arranged anglewise. The stakes should be surrounded with strands of barbed wire, or wire netting will suffice. *E. Molyneux.*

ANSWERS TO CORRESPONDENTS.

BROWN ROT IN APPLE TREES. *T. J. H.* If you find any dead leaves hanging on the trees through the winter, remove them, and cut out any dead shoots or spurs. These should either be burnt or dug into the ground. During the winter spray the trees with copper sulphate (98 per cent. purity), 1 lb. in 10 gallons of water, or with lime-sulphur mixed according to the maker's directions for winter spraying. In the spring, as soon as the flowers have shed their petals, spray with lime-sulphur, summer strength, and spray again a fortnight or three weeks later. You will then have done all that is possible against brown rot. Lime-sulphur may be purchased in concentrated liquid form.

BUILDING A GREENHOUSE. *T. S. C.* If a 14-inch buttress is built into the back of the 9-inch wall at every 6 feet the wall should be strengthened sufficiently. The wall-plate at the top of the wall will add support also. Well-seasoned Red Deal, with 21 oz. glass for the roof and 15 oz. glass for the front and ends, will provide a substantial house that, if kept regularly painted, will last sound for many years.

CATTLEYA FLY. *J. T.* The Cattleyas are suffering from an attack by the Cattleya Fly (Isosoma orchidearum) (see fig. 59) and also by the Orchid Cecid (Cecidomyia Cattleyae). Both these pests are frequently very injurious to Orchids, therefore the houses containing Orchids liable to attack should be fumigated at brief intervals, in order that the young flies may be killed before they are able to do any harm themselves or deposit eggs. In the case of a very bad attack of Cattleya Fly, where one or more growths have become much swollen and infested, it may be advisable to cut out and burn such growths, but otherwise the best method of exterminating the pest is the one described by Mr Thurgood in *Gard. Chron.*, Feb. 9, 1907, p. 94, i.e., fumigating the house twice a week for five months. At the end of this period all the eggs deposited have hatched, passed through the larval stage, and become perfect flies, and these latter are killed by the subsequent fumigation.

CYANIDING TOMATO HOUSES: *G. H.* On p. 141 we gave instructions for cyaniding fruit houses, and the same general instructions hold good in the case of houses containing Tomatos infested with White Fly (Aleyrodes vaporariorum). The foliage of the Tomatos should be dry when cyaniding is commenced. As the fumes are deadly poisonous, every care must be taken to keep the house locked, and as airtight as possible, during fumigation. Subsequently, open the ventilators from the outside, and the doors if weather permits. No member of the staff should be allowed to enter the house until the fumes have dispersed. For White Fly on Tomatos, the materials for each 1,000 cubic feet should be 1¼ ounce sodium cyanide, 3½ fluid ounces sulphuric acid, and 10½ fluid ounces water; temperature not above 55°; exposure 40 minutes. Repeat the fumigation at intervals of two days until all eggs are hatched and flies killed.

MOTOR TRACTOR PLOUGHS; *D. M. G., Amsterdam.* We do not know of a motor driven plough with so low a power as 1·4 horses. The Titan tractor is 20 h.p., and will, in addition to ploughing, scarifying, cultivating and rolling the land, draw two self-binder corn-cutting machines; it will manage road haulage up to

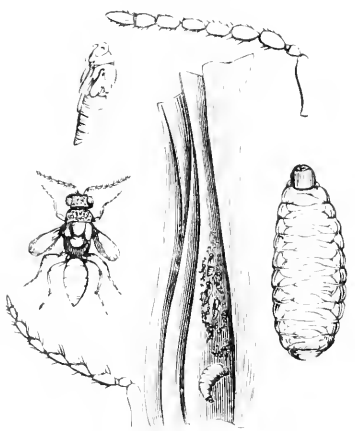

FIG. 59.—CATTLEYA FLY (ISOSOMA ORCHIDEARUM).

4 or 6 tons, and will drive a drum to thresh corn quite easily. The price is £385, delivered at any railway station in England. A week's tuition is given by the agents in its management, and in ploughing as well. The total weight is approximately 2¾ tons. With one four-furrow plough six acres per day of ten hours can be ploughed. The shares vary in width, from 10 inches to 14 inches, according to the type of plough. The former is sufficient for good work, as it cuts off Thistle roots, and the Thistle is the most difficult weed to eradicate. Approximately 5 gallons of paraffin oil is required per day. The machine is started with petrol. In Hampshire, tractor ploughs are much used on all kinds of soil, but the lighter the soil the easier they work. Hilly ground is, generally, not so suitable as flat ground for any kind of tractor.

NAMES OF FRUITS: *W. B.* 1, evidently a seedling from Ribston Pippin; 2, Crimson Queening; 3, Annie Elizabeth; 4, Warner's King.—*S. B. J.* 1, Hoary Morning; 2, Waltham Abbey Seedling; 3, Cox's Pomona; 4, Domino. *E. B. C.* 1, Mank's Codlin; 2, New Hawthornden.

NAMES OF PLANTS: *Col. Northbeach.* No. 9, Crataegus punctata.—*Nimrod.* 1, Crataegus macracantha; 2, Passiflora coerulea, var.; 3, Echium candicans var.

LOVAGE.

THERE is much of interest connected with the old English herb Lovage, which has been thought to resemble in some degree our garden Angelica. "My fancy form'd Thee an angelic kind" (*Pope*) might well be applied to either herb, or also to Myrrh-like "Sweet Cicely."

Its repute as a domestic medicine seems not to have been countenanced by doctors. It was used as a homely remedy for stomachic complaints, especially for cases of colic and flatulence in childhood; no extravagant claims were made on its behalf as in the case of Angelica, which was professionally prescribed even as a cure for the bite of a mad dog! Probably the origin of Elecampane as a rival drug arose from the absurd superstition of "signatures," but undoubtedly the medicinal property of Lovage was founded upon its pleasing aromatic odour; probably its very name is significant of a prior prevalent idea of virtue, as was undoubtedly the case with Angelica. The latter herb is now classified botanically in the genus Archangelica; thus promoted to archangelic rank, some have supposed it to be dedicated to the Archangel, St. Michael, of whom one feast day is on May 8, when the plant would (in old style) be in flower, but his chief festival, of course, is Michaelmas Day. However, the appropriate Archangel should be St. Gabriel, for the herb has also been associated with the festival of the Annunciation. The semi-pagan Letts of the south-east Baltic shore still, perhaps, associate this herb with their Goddess of Love.

In culinary uses Lovage was always at a disadvantage in competition with Angelica, because it does not furnish such stout, lengthy, and succulent leaf-stalks ready to hand out of the garden.

Then, again, at one time there prevailed some confusion or mistake with misapplications of the name, which will be best understood after seeing all the various competitors for sharing the name set forth as follows:—Old English Lovage, Levisticum officinale; Sea Lovage, or Scotch Parsley, Ligusticum scoticum; Black Lovage, or Alexanders, Smyrnium Olusatrum; Bastard Lovage, a species of the genus Laserpitum; Water Lovage, a species of the genus Oenanthe.

There are other names and variations of the above names popularly given to these herbs; for example, the true Lovage has been called Cornish Lovage, and its chief rival has been termed Scotch Lovage. An author who credited Scotch Parsley with being the herb "Lovage" termed the old English plant "Italian Lovage." Furthermore, the name Lovage has been misapplied to a kind of Milfoil or Yarrow (Achillea ligustica), a plant quite outside the Umbelliferæ family. Similarly, the appellations Angelica and Archangelica have been in a less degree obscured by the latter being connected with the common Yellow Dead Nettle. The public-house cordial named "Lovage," now not much in vogue, probably owes such merit as it may possess to Milfoil and Tansy rather than to the herb after which it seems named. There are other allied herbs in the genera Peucedanum and Angelica which have no real claim to share in the name, but the Spanish Angelica heterocarpa does very closely resemble Levisticum officinale in foliage and perennial habit of growth.

It was once supposed that the true Lovage was never found wild except in the extreme south-west of England, but it is said to be identified with a South European herb growing wild in Northern Greece and the Balkans. It is recorded in Withering's *British Plants* how at one time the true Lovage was believed to have become extinct; and how in 1793 it was rediscovered in a field near Bodmin. Cattle are so fond of this plant that it is liable to become scarce in any pastures where they graze. It is sometimes cherished in gardens for its ornamental foliage, as well as its pleasant odour; it is perennial, and of easy culture.

Sea Lovage growing on the cliffs and rocky shores of Scotland is said to be eaten as a vegetable, but its use thus does not meet with general favour.

Black Lovage derives its appellation from the external colour of its roots. The whole plant is nauseous; but, however, as in the case also with Coriander, the seeds, when fully ripe, are very sweetly aromatic, and much valued for pleasantly flavouring confections of Senna and disguising the taste of other medicinal preparations.

Bastard Lovage is not a native of Great Britain. The species respectively comprised in the genera Laserpitum and Ligusticum have, *prima facie*, much in common regarding foliage, manner of growth, and aromatic odour.

Water Lovage is nearly related to Hemlock, Water Dropwort, and all the species of Water Dropwort (Oenanthe) are suspect or actually poisonous for horses and cows, but it has been stated that one species, called Horsebane, is eaten by sheep. Some doubts which have arisen about the virulence of Water Dropwort poisons are explainable by a belief that, when growing in more northern latitudes, their deleterious qualities are modified, and much of the poison evaporates when the plants are cut and more or less dried.

The utility of the aromatic seeds of Angelica and Lovage is negligible, inasmuch as they are excelled by so many others of our native herbs. These latter, although so estimable and in established use, are rather outrivalled by imported seeds and spices of a more powerfully aromatic character, such as Cardamom and Grains of Paradise.

Trial may disclose that economic utility in the way of salutary and tasty food may be obtained by using the plants of Angelica, Lovage, and probably also the Cow Parsnip (Heracleum Sphondylium), after the manner of Seakale. Sea Lovage and other allied herbs, when treated like Celery, have proved quite inferior.

There doubtless are practised some unavowed employments of Angelica and other herbs for enhancing the flavour of potable concoctions and edible confections. The late Mr. Robertson, of Chelsea, jam-maker and confectioner, deemed such employment very advantageous, and he did not restrict himself to using only Archangelica officinalis, of which species the supply was apt to run short.

Gin distillers use Angelica in combination with Juniper berries, or in partial substitution thereof. From most ancient times Angelica has been one of the chief flavouring ingredients of beverages and liqueurs, but probably it will be known only to a few people that the Muscatel Grape-like flavour of some wines made on both sides of the Rhine is (or is suspected to be) due to the secret use of Angelica. In all these economic uses Lovage can only aspire to take a second place of honour.

Another very old practice is to put a small portion of the fresh herbs into the pot in which fish is boiled. Perhaps the chef of King George III. advantageously treated fish not too fresh in this way.

Several very entertaining books have been written on the myths and legends of plants and flowers; yet the authors, for the most part collecting from many remote countries and old classic books, have but little to say about Lovage. Angelica, however, being dedicated to some Archangel, was naturally associated with the Blessed Virgin Mary and the Annunciation. Owing to its unprepossessing blossom, painters have not portrayed it, nor have poets sung its praises. It is the same with that fantastic literature, the language of flowers; the gay ones are favoured in this kind of imaginative nonsense; genuine folklore is not much found therein, the most part being modern make-up.

A very excellent oldish book, Lindley and Moore's *Treasury of Botany*, contains a plate giving a typical landscape view of "Kamtchatka"; therein tall flowering or seeding plants of Angelica are boldly apparent, rather dwarfing the Birch bushes and stunted trees which are reported to be a leading feature of

that almost Arctic country. These far-northern plants would probably be A. communtata; A. Keiskei grows in Japan. It would be very interesting to learn what the Japanese may be able to tell us about this and like herbs native to their country.

An error in my note on Angelica published in *Gard. Chron.*, September 7, 1918, requires correction: on page 95, in the middle column, line 10 from the bottom, the parenthetical qualification "(leaves)" should read "(not the leaflets of the leaves)." A kind of herbal tea is indeed made of the leaves, but then these have been *previously dried*. The leaves of Lovage are much milder, and a decoction thereof has a very agreeable odour.—*G. Haulstone Hardy (Major, Old House, Twickenham*

DAHLIA CAMBRAI.

THE beautiful, scarlet Collerette Dahlia illustrated in fig. 60 was awarded the R.H.S. Award of Merit and the National Dahlia Society's First-class Certificate on September 10, 1918, when shown by the raiser, Mr. J. A. Jarrett, under the name Peroune. Messrs. W. Treseder and Sons had already given the name Peroune to a somewhat similar, but distinct, variety, and in order to avoid confusion, Mr. Jarrett's flower has, with the permission of the two societies which made the awards, been renamed Cambrai.

The flower is of very regular outline, and the outer florets are cup-shaped, so that the scarlet colouring appears richer or softer according to the pose of the bloom. The "collar" is yellow, slightly flushed with scarlet. The blooms are borne on long, stiff stems, and the variety makes a bold and effective plant for gardens.

Mr. Jarrett, the raiser of Cambrai, is an amateur grower who has won many successes as a raiser and exhibitor of Dahlias, both in the amateur and open classes. At the National Dahlia Society's exhibition in 1917 he won first prizes in each of the seven classes in which he competed, and this year he again excelled in the open and amateur classes for both Paeony-flowered and decorative Dahlias. He has also established the further amateur record of gaining on two separate occasions this year no fewer than three R.H.S. Awards of Merit and three First-class Certificates of the National Dahlia Society, for seedling varieties raised in his garden at Anerley.

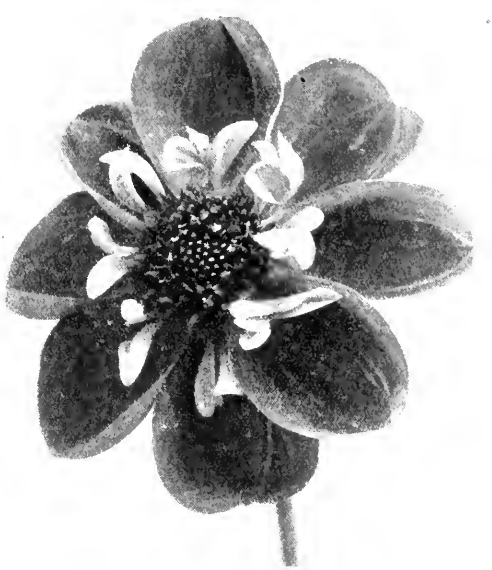

FIG. 60.—DAHLIA CAMBRAI: A SCARLET COLLERETTE VARIETY WITH YELLOW "COLLAR."

ORCHID NOTES AND CLEANINGS.

LAELIO-CATTLEYA ELEGANS.

THIS very variable hybrid, originally imported from the island of Santa Catherina, Brazil, where it was growing with Cattleya Leopoldii and Laelia purpurata, was long regarded as a true species, and was described and figured by Chas. Morren in 1848 as Cattleya elegans (*Ann. de Gand.*, iv., p. 93, t. 185). Although this parent was regarded as a doubtful species in some gardens, and placed under Cattleya, or Laelia, the latter title still having a strong hold in garden nomenclature, its hybrid origin was not suggested until 1877 (*Gard. Chron.*, 1877, II., p. 424), and not authoritatively recorded as Laelio-Cattleya until many years later (*Gard. Chron.*, 1889, I., p. 619). The complications were further increased by the inclusion of L. C. Schilleriana (L. purpurata × C. intermedia), imported with it under the same name.

It remained for Eustace F. Clark, Esq., Evershot, Dorset, by flowering the home-raised cross between Cattleya Leopoldii and Laelia purpurata in 1911, to prove the suggested parentage of the imported natural hybrid, the record being soon afterwards verified by Messrs. Jas. Veitch and Sons.

Mr. Clark now sends a very pretty form, which differs from the original flowered by him. The lanceolate, recurved sepals are whitish-lilac on the face and tinged with green on the reverse side. The much broader petals are tinged with lilac and veined with light mauve. The lip, which has the base closing over the column and the erect tips of the side lobes indicative of C. Leopoldii, is blush-white on the lower half, the interior being tinged with yellow, and bearing thin, purple lines running into the broad, undulated, violet-purple front lobe. Enforced cool treatment is said to have interfered with the full development of the flower, which should be even better when the proper heating of the Orchid house is possible.

LOWIARA INSIGNIS.

FLOWERS of this rare hybrid are sent by Messrs. Stuart Low and Co., who first exhibited this remarkable cross between Sophronitis grandiflora and Brasso-Laelia Helen (B. Digbyana × L. tenebrosa) at the meeting of the Royal Horticultural Society, Nov. 19, 1912, the raiser's name, with the suffix "ara," being used for the generic title in accordance with the rule relating to the nomenclature of new combinations in multi-generic hybrids. Sophronitis grandiflora was the male parent, and in the tint of the sepals and marking of the lip this parent can well be traced, but in size and shape the flower is nearest to the seed-bearing parent. The sepals and petals are 2½ inches long, the latter being more than 1 inch in width; both are coloured light copper-red. The lip, which is well formed, is 2 inches in length, undulate at the margin, and coloured light rose-pink with darker veining and yellowish base and disc.

THE MARKET FRUIT GARDEN.

THE month that has just passed must have been one of the wettest Septembers on record. At my station there were only nine days without rain, and the total fall for the month was no less than 6.23 inches. Towards the middle of the month there was a period of nine rainy days in succession, and on the 29th exactly 1 inch fell in the twenty-four hours. My records go back only eight years, but in that time there has been no approach to such a wet September, the nearest being in 1912, when the total rainfall was 3.48 inches. Naturally work was much hindered, but not so much as might be imagined, because most of the rain fell at night. Had there been a normal crop of fruit to harvest the constant interruptions to picking would have been serious. As it was, the appearance of late Plums was spoiled, rain ruining the "bloom," whilst the gathering of Cobnuts has had to be delayed so long that many of the nuts are falling from the trees. Weeds have grown apace, and it is much to be hoped that October will be dry enough to render hoeing effective.

PLANTING PREPARATIONS.

Preparations are being made for the planting of a new orchard of 3½ acres. This land was under grass in 1917. It was somewhat elaborately drained, ploughed, and subsoiled, and a good crop of Potatos has recently been harvested from it. This crop forms the best preparation for orchard planting, as it pays for liberal manuring with dung, and leaves the land clean and in good condition. Moreover, if mid-season Potatos are grown, they are lifted in ample time to get the ground ready for the trees.

It is advisable to lime or chalk land intended for fruit trees, and we have usually given a heavy dressing of small waste chalk from lime kilns within carting distance. These kilns are now closed, owing to shortage of labour. It would, of course, be possible to buy ground limestone or caustic lime, but I prefer to try basic slag at the rate of 10 cwt. per acre. This fertiliser contains enough lime to last the trees for some time, and I hope that the phosphates will tend towards the production of firm, fruitful wood.

THE BEST FORM OF TREE.

Considerable difficulty has been experienced in getting the necessary trees. The Army has drawn so many skilled men from the nurseries that little propagating has been done, and stocks have become low. In order to obtain trees for this little orchard of 3½ acres it has been necessary to go to no fewer than five nurseries. It is true that I was looking for a form of tree that is not commonly in request—a bush-shaped tree on an 18-inch leg. In many nurseries bushes are trained without any stem at all, or, if they have one, it is not more than

12 inches long. A legless tree probably suits private gardens very well, but it is undesirable in a market plantation, because a band of wire netting is necessary to protect the bark from rabbits. It is, of course, possible to fix netting all around the plantation, but this is much more expensive and a perennial nuisance, being always smothered with weeds and liable to be broken down. Other advantages of a leg are that it keeps the lower branches off the ground and facilitates the work of hoeing and digging.

Bushes versus Standards.

The first orchard planted here was of bush trees on the Paradise stock. Many of them were stunted, sour-covered trees when they arrived: they were not pruned sufficiently for the first few years, and the planting was followed by two seasons of prolonged drought. As a result many of the trees practically stood still and looked as if they never would come to anything. It was decided, therefore, that bushes on the Paradise stock would not thrive on this somewhat poor land, and the other fields were planted with half-standards on various stocks, mostly Crab. I have decided on a return to bushes for several reasons. In the first place, the original orchard did go ahead in course of time, and is now invariably the most profitable on the farm. Low bushes are much more convenient for spraying, pruning, and gathering of the fruit, whilst they are less exposed to the wind, and so give less trouble with windfalls. Many people would say that half standards allow greater freedom for horse cultivation, but my horseman prefers to work amongst bushes, provided that they are not planted too closely together. The main branches of half-standards come out at just the right level to catch the horses, and, as they are stiff, the result is they are often broken. Amongst bushes, only the slender ends of the branches are likely to touch the horses, and these offer little resistance. Then there are several advantages in the use of the Paradise stock. The trees come into bearing earlier than on the Crab or free stock, and produce finer fruit, whilst their roots keep nearer to the surface. This last is an important point here, as the subsoil is of an undesirable nature, and it is noticed that the trees are very liable to canker when their roots get down into it.

Free-growing Varieties.

Eighteen years of fruit growing here have taught us which varieties of Apple can be planted on this somewhat poor land with prospects of success. This is a lesson which every grower must learn for himself, as no one can say with confidence how any variety will behave in a particular district, unless there are other orchards on similar soil in the neighbourhood. Here only very free growing varieties are profitable. The following is my selection for the new orchard: Bramley's Seedling, Blenheim Pippin, Royal Jubilee, Charles Ross, Newton Wonder, Early Victoria, Rival, and Devonshire Quarrenden. The first five have proved their worth here as free growing and very healthy varieties. Early Victoria and Rival have been grown for only two or three years, but they give such good promise that they are included. Devonshire Quarrenden is an experiment. All of these are to be on Paradise stock with the exception of the very prolific Early Victoria. In spite of this they will be planted 18 feet apart each way. Previously we have planted at 12 feet apart, but this proves much too close for these free-growing varieties, even on the Paradise stock. If allowed ample space the trees bear fruit all round, instead of only on the top, as happens where closely planted trees grow into one another. Moreover, I believe that, where the soil suits, Paradise stock better than free or Crab stock, the former will give a tree with just as big a head. Certainly some of the largest trees here are on Paradise. Were their bulky heads perched up on 4 foot stems in the form of half-standards, they would be considered unmanageable, and efforts would be made to keep them within bounds. As it is, their topmost branches are reached for pruning and gathering without much difficulty. Trees planted 18 feet apart certainly look lost at first, but this does not matter when the intervening spaces are planted with Black Currants or some other small fruit. I expect to find that Black Currant bushes have a considerably longer life of usefulness in this orchard than they have between trees planted closer.—*Market Grower.*

CITRUS TRIFOLIATA (SYN. AEGLE SEPIARIA).

Whether in flower or fruit this very strongly characterised shrub, or small tree, is one of the most ornamental that can be grown. In May it is covered with large, sweetly scented white flowers like those of a Citrus. It is commonly known as Citrus trifoliata, under which name it is figured in *Bot. Mag.*, tab. 6,515, and in autumn, in districts where it flourishes, it is covered with yellow, downy fruit which much resemble small Oranges (see fig. 61). It is, perhaps, the most spiny shrub that can be grown in a garden, and the spines, which are straight, sharply pointed, and green like the stem, are from 1 to 2 inches long. Nothing could form a more formidable hedge, but it is not everywhere, perhaps, that the plant can grow with sufficient vigour. In the Cambridge Botanic Garden, where the photograph from which the illustration was prepared was taken, it grows with great vigour against the end of a Fern-house, but a specimen planted on a border not many feet away grew slowly. The plant appears to be absolutely hardy.

By crossing *C. trifoliata* with the common Orange a hybrid, known as the Citrange, has been raised in France with the object, it has been said, of providing an Orange that would flourish in a climate that is too cold for the common Orange. This hybrid was raised some years ago, but I am aware of no report which shows that it has attained a sphere of usefulness. Citrus trifoliata is a native of China and Japan, and is described as one of the most striking Japanese plants ever introduced. It can be raised from British-grown seed, or cuttings of half-ripened wood may be rooted. The

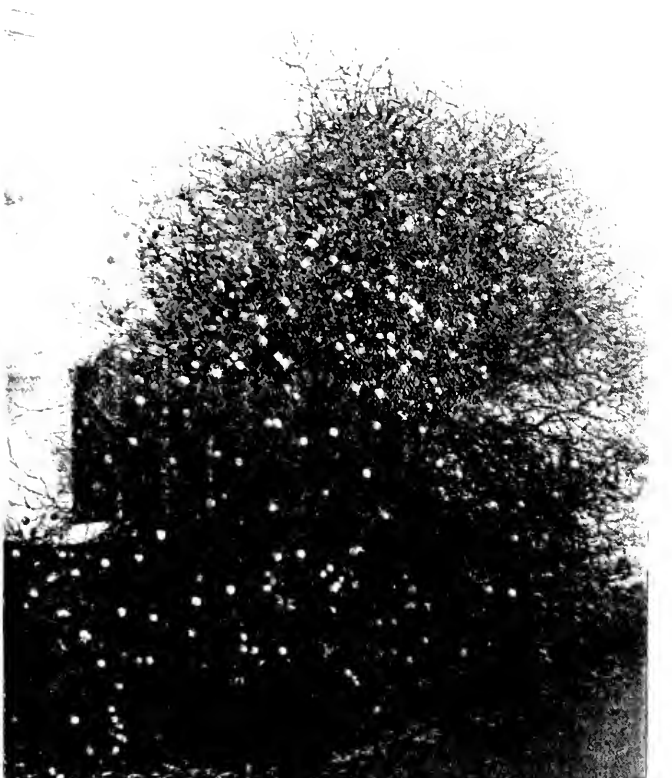

Fig. 61.—Citrus trifoliata fruiting in the Cambridge Botanic Garden.

genus Aegle, to which the plant appears most correctly to belong, differs from Citrus only in having the stamens free from one another. [The *Index Kewensis* refers Aegle sepiaria to Citrus trifoliata. Eds.] The leaves are of interest as explaining the structure of an Orange-leaf. They are trifoliate, and the lateral leaves make a joint at the point of attachment. In the Orange there is a joint where evidently the lateral leaves belong, but obviously have been suppressed. Members of the Rutaceae with compound leaves are, of course, frequent.—*R. Irwin Lynch, Botanic Garden, Cambridge.*

[The illustration in fig. 62 shows the fruits natural size, also the trifoliate leaves and very formidable spines. Eds.]

BULB GARDEN.

CROCUS IRIDIFLORUS.

FLOWERING in the end of September and in October, Crocus iridiflorus is one of the choicest of the autumnal flowering Crocuses, vieing with *C. speciosus* in beauty, and ranking with it as one of the most reliable of these autumnal species. It is delightful as this is written, on the last day of September, when, after a period of rainy weather, a brighter day than usual has induced the plant to open its flowers. Comparing these blooms with the coloured plate in that *magnum opus* of Mr. George Maw, *The Genus Crocus*, one is struck with the inferiority of the colouring in the illustration compared with that of the flower itself. The colour is a rich purple on the outer segments, while the inner ones are of a clear lilac with purple lines. The anthers are orange, the filaments white, and the stigmata rich purple, the whole combination of colouring being exceedingly beautiful. As Maw remarks, this is the only Crocus species with purple stigmata. A noteworthy feature of the flower is that the inner segments are smaller than the outer ones, and the general effect is like that of some of the Irises, hence the name iridiflorus. The name of *C. byzantinus* has also been given to this Crocus, but, although it has priority in point of time, it is misleading, and there seems a pretty general agreement that iridiflorus should be accepted. *C. iridiflorus* is a native of Hungary, the Banat, Wallachia, etc., and is hardy in this country. The corms should be planted about an inch deep. *S. Arnott.*

"BLINDNESS" IN THE DOUBLE WHITE NARCISSUS.

Now that the time for planting Daffodils has arrived, it may be useful to direct attention to the so-called "blindness" in Narcissus poeticus fl. pl., for the malformation is among the perpetual worries of the gardener. With all the Narcissus tribe the embryo flower for the ensuing year is made with the maturing of the leaf of the preceding year; a fact which renders weather conditions not a little responsible for either good or indifferent flowering. In this connection it will be remembered that the double white Narcissus referred to is probably one of the last to flower, hence it has to complete its growth and lay the foundation of the next season's flowering virtually during high summer time. With great heat or continued drought prevailing, it is easy to see that this would be imperfectly done, with "blindness" in the following year as the inevitable result. Many years ago I began experimenting with a view to discover, if possible, the cause of the trouble. Growers of the variety variously attributed the failure to "drying winds at flowering time," "spring frosts," or "malnutrition." My soil at the time was light loam over gravel, which became very dry in summer, the season of growth in the plant being considerably shortened in consequence. Convinced that this, in conjunction with summer heat and absence of root moisture, were the contributory causes of the blindness, the aim of the experiments was to reverse these conditions entirely. Some of the bulbs were grown in pits, in pots, the latter standing in saucers of water, and others were placed in a low-lying bog bed, into which much surface water entered. Others were planted later near the side of a pond, where, once they had become established and with roots in constantly cool, moist, and often wet ground, blindness was unknown. Since those early experiments I have frequently planted the bulbs in ground often flooded in winter time, with the best results. Planted in deep, cool, or moist ground, the growing season of the plant is lengthened and its other functions following in due order immunity from blindness is practically secured. Lifting and drying is unsuited to this variety, because of a propensity to continuous rooting, hence permanently planted bulbs give the best results. This variety, too, like *N. maximus*—another lover of cool, stiff, moist soils—succeeds best if deep planted, and a minimum depth of 6 inches should be allowed. *E. H. Jenkins.*

AUSTRALASIA.

PHOENIX CANARIENSIS IN AUSTRALIA.

OWING to war conditions, my copies of the *Gardeners' Chronicle* reach me at irregular intervals, and it was only to-day that I read Mr. J. H. Maiden's reply to my communication published in your issue of March 3, 1917. In Mr. Maiden's first communication to you he distinctly stated that nothing was known in Australia about the origin of Phoenix canariensis, and now he professes to know everything about this Palm. My letter, that appeared in your issue of March 3 of last year, supplied the correct information about the introduction of the seed of Phoenix canariensis to Australia, and its subsequent planting, and the information concerning the original source of the seeds has since been confirmed by the authorities at Kew. I also stated that Mr Charles Moore had informed me that when Sir William Jackson Hooker and Sir Joseph Dalton Hooker (the latter name was deleted from the letter-press, although it appeared in my manuscript) were directors at Kew they had supplied the seeds of most of the Palms, including Phoenix canariensis, which I first planted in the Garden Palace Grounds, Sydney. I probably knew Mr. Moore longer than any man now living, and I had considerable official intercourse with him. First, when the Government of New South Wales instructed me to re design many of the shrubberies and flower beds in the Botanic Gardens, Sydney, and afterwards when they appointed me to take charge of the Garden Palace Grounds, much of which I designed, laid out, and planted. I have in my possession a letter from Mr. Moore in which he refers to the important professional work I had been engaged in at the Botanic Gardens and Garden Palace Grounds, and the great skill I had displayed in carrying it out. It was my work in those public gardens that attracted the attention of the late Hon. Sir Alfred Stephen, G.C.M.G., Lieutenant-Governor of New South Wales, and of the late Hon. Dr. James Norton, LL.D., M.C.L. (member of the Legislative Council), who appointed me to re-design, lay out, and beautify Hyde Park, Sydney, and amongst the many improvements I effected in that public park was the planting of the groups of beautiful Palms now growing there.

In *Gard. Chron.*, Oct. 6, 1917, Mr. Maiden states "that Mr. Charles Moore was the most autocratic of men, and never was known to give anyone a free hand in anything." During my long intercourse with Mr. Moore, both socially and officially, I found him at all times most considerate, and I was indebted to him for many valuable suggestions in the course of our official work.

When Mr. Maiden's first letter appeared in the *Gardeners' Chronicle* concerning Phoenix canariensis, the leading Australian landscape gardeners and nurserymen spoke to me on the subject, and said that "if Mr. Maiden had addressed a letter to the local Press, or to myself, he could have obtained all the information he desired about the Palms I planted in the Garden Palace Grounds." If this had been done, it would not have necessitated him writing to you about alleged conversations with the late Mr. Camfield, and who had no more to do with planting the original group, and the only one, of Palms in the Garden Palace Grounds than the proverbial "man in the moon." The last paragraph of Mr. Maiden's letter tries to obscure facts by the introduction of matters not relevant to the subject. *Fred. Turner, Chatswood, Sydney, July 17, 1918.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Cucumbers. — Old Cucumber plants which have been in full bearing for some time, and show signs of declining vigour, should be discarded. The restoration of old plants, either by thinning the growths or stimulating the roots at this season is rarely satisfactory. Young plants make better progress, but from this date onward they require careful treatment in order to make healthy, short jointed growth that will produce fruit freely during the winter. Maintain a sweet, moist atmosphere by damping the floor and walls of the house frequently. Grow the plants in a moderate temperature, and do not over-crop them. Stop the shoots frequently, and train them thinly and regularly over the trellis in order that the light and air may enter all parts of the house. Frequent light top-dressings of fresh compost applied warm will encourage the roots to grow and keep them healthy. An excellent compost for winter Cucumbers is formed of two-thirds light, rich turf, free from worms, and one-third old lime rubble, with a good sprinkling of bone-meal and a dash of soot. The soil should be mixed thoroughly, and placed in a warm, dry corner for future use. Plants growing over the water-pipes must be watered carefully; sufficient water should be used to moisten the whole of the soil and keep the lower roots thoroughly moist. Later plants intended for cropping early in the spring should be encouraged to grow steadily. Let them have plenty of light and a little air on all favourable occasions.

Lettuce and Endive. Lettuces which are ready for use, also those for cutting early in winter, should be lifted and placed in cold pits until required for use, or where shelter can be readily afforded them. Small seedlings of later-sown batches of Lettuce and Endive should be pricked out into cold frames or under the shelter of walls. Endive should be planted 1 foot apart each way, and encouraged to grow quickly by stirring the soil frequently with the Dutch hoe in fine weather. All available frames should be filled with Lettuce, while the hardiest kinds, such as Bath Cos and the hardy Cabbage sorts that are sown thinly to mature where they are sown, should be thinned, and the soil amongst them stirred to get them well hardened before winter. Dust the plants lightly with soot at short intervals as a deterrent to slugs.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Miltonia. — Plants of Brazilian Miltonias, such as M. Regnelii, M. Binotii, M. spectabilis and M. s. Moreliana, should be kept rather dry at the roots after passing out of flower. Just sufficient water should be given to prevent shrivelling of the leaves and pseudo-bulbs, and this treatment must be continued until growth becomes active again in the New Year. M. cuneata, M. Clowesii and M. candida are developing their flower-spikes; as they pass out of flower they should be given the same treatment as recommended for the others. These plants are very subject, and especially at the present time, to attacks of red spider; as a precaution the leaves should be sponged occasionally with a solution of soft soap and tepid water. M. Roezlii, its variety alba and M. Phalaenopsis are of very delicate constitution, and require very careful treatment. They require a slightly higher temperature than either of the above-mentioned species or M. vexillaria, and succeed best in the shadiest and warmest position in the Cattleya house. Any plants that have commenced to grow may, where found necessary, be given fresh rooting materials. The compost should consist of equal parts of Osmunda fibre or A1 fibre and Sphagnum-moss, cut into short portions, with a liberal addition of crushed crocks.

Aerides, Angraecum, and Saccolabium.—Many plants of these genera that flower in the spring and early summer will have completed their season's growth soon, and the supply of water at their roots should be reduced gradually. Although these Orchids never cease making leaf growth, it is important to allow them a short period of rest. When the plants are in active growth the compost should be watered sufficiently to keep the moss on the surface green and fresh, but from now onwards through the winter the moss should be allowed to dry to a greenish-yellow colour before water is applied. Such of the cool growing Aerides as A. crispum, A. Lindleyanum, A. crassifolium, and A. Warneri are still growing actively, and for some time to come should be kept moderately moist at the roots, and grown in a shady position in the Cattleya house. Angraecums that are in full growth, including A. sesquipedale, A. Eichlerianum, and A. pellucidum still require plentiful supplies of water, whilst A. eburneum and A. Monteirae are sending up flower-spikes, and should also be kept moist at the roots.

THE HARDY FRUIT GARDEN.

By Jas. Hudson, Head Gardener at Gunnersbury House, Acton, W.

Root-Pruning.—The root pruning of trees needing this operation should be commenced at once, as an early start will enable the roots to make good growth before severe frosts occur. First finish the pruning of the branches, but do not prune severely, for if mild weather continues there would be a danger of the plants continuing to grow freely, and especially in the case of Pear trees on the Pear stock. Remove the sappy shoots, then exercise judgment in the case of the more ripened wood. In the case of large trees, the time-honoured system of root-pruning only one half of the tree one year and the other half in the following season is advised. It is far better to root prune than to severely prune the branches. To do the latter would often result in canker. Procure a quantity of good soil that has not been in contact with the roots of fruit trees, and work this around, under and above, the roots. Shorten all strong, sappy roots as the work proceeds and replace the tree in its old position, unless it is seen that moving it is desirable, such as in the case of bush trees and pyramids that may be growing too near the pathways. I do not advise the use of manures of any kind. After pruning the roots see that the trees are made firm in the soil and well watered. Then secure them to stakes to guard against disturbance during strong winds.

The Planting of New Orchards.—There comes a time when it is expedient to consider the necessity of preparing ground for planting new orchards. To attempt to renovate an old orchard when it is evident that the trees are on the decline is not profitable. The planting of Apple trees after Apple trees is a bad practice, and the same is true of other kinds of fruits. I do not refer so much to orchards planted for market purposes as to those in private establishments. I recommend that a new orchard be only partially planted the first season and completed the following year, when the ground has been entirely broken up. For the first season, now that labour is scarce, if the new orchard is on pasture land, the grass may be retained and broken up as time permits. I prefer pasture land to arable land that may have been either badly cultivated or heavily cropped. In private orchards the mixing of standard trees and bushes, such as Currants and Gooseberries, is not to be recommended. The bush fruits may, in most cases, be grown in the kitchen garden. Considerable discretion needs to be exercised in the choice of a site for an orchard. The soil may not be all that one could wish, but with due care it may be made suitable by draining, which, in the case of heavy and waterlogged ground, is essential. If time presses it is not essential to do this immediately, for the trees may be planted and the drains laid in the early spring following. It is not expedient to drain light land, nor it is so essential if the land slopes, so that superfluous water drains away naturally. An orchard should be exposed to the south and west. If old brick rubble and mortar rubbish are available, make good use of these materials in the soil, more particularly in heavy land. Place some of the brick and mortar rubbish at the bottom of the hole, and place turves upside down upon them. Do not use animal manure, even in the poorest of soils. Rather apply loam of better quality than that of the orchard. Make the holes deep and wide. When planting is completed apply a mulch, which in time, by hoeing, will become well mixed with the soil. For most orchards in private establishments dwarf trees on the Paradise stock are to be preferred to any other kind for Apples, whilst Pears worked on the Quince stock are invariably the best to plant. Bush Apples are more suitable than pyramids, but for Pears the pyramid tree is best. The best distance at which to plant is 12 feet, and the trees should be arranged quincunx fashion. For standards a distance of at least 24 feet is advisable. If the Apples are strong growing varieties a space of 24 feet should be allowed. With standards at this distance the ground may be filled with bush fruits as occasion requires.

THE FLOWER GARDEN.

By R. P. Brotherston, Gardener to the Earl of Haddington, Tyninghame, East Lothian.

Dahlias are of conspicuous value during the autumn, as the plants fill large spaces at little cost of time and labour. The tubers should be lifted before the stems have been frosted, with as much soil as can be retained preserved on them. There is no better preservative than such soil to keep the tubers from shrivelling. The roots are stored in heaps just like Potatos, and, with the exception of Pompon sorts, which I find rather liable to rot, they come through the winter in perfect condition.

Hybrid Lobelias.—These plants are very erratic in their winter behaviour, sometimes great losses occur, at other times the losses are insignificant. They are all but hardy, and I have known plants left in the ground come through the winter with fewer losses than those preserved under glass. Like Montbretias, they cannot be kept too cool, and ordinary frost does them no harm. A cool frame, on the floor of which the clumps may be set closely together, with some light soil or leaf mould intermixed to fill interstices, is the best place for storing them in. The soil should not be shaken from the roots, but, on the contrary, good balls should be secured on lifting and preserved intact.

Montbretia.—There is a difference in the hardiness of Montbretias, and, as a rule, it is better to err on the side of safety by lifting the corms annually, especially of the newer varieties, than to risk losing them during lengthened periods of frost. It must be remembered that growths develop very early in the year, and the plants may be lost altogether if the corms are stored in a place much above freezing point. They are, indeed, so nearly hardy that were we to have only ordinarily severe winters there would be no advantage in lifting them beyond the need of giving more space when the growths become so congested as to spoil the production of flowers in profusion.

FRUITS UNDER GLASS.

By W. J. Grise, Gardener to Mrs. Dempster, Keele Hall, Newcastle, Staffordshire.

Early Peaches and Nectarines.—The trees in the early Peach and Nectarine houses should be examined carefully for any faulty or overcrowded shoots that may have been overlooked when the leaves were on the trees. If the summer pruning was efficiently carried out very little further pruning will be required. The branches should be let down, carefully tied into bundles, and clung to the trellis or wires preparatory to thoroughly cleansing the woodwork and glass of the house with soapy water. A mixture of quicklime, sulphur, and a little soft soap forms a suitable wash for the walls. The cleansing of the trees is a very important operation, as every shoot should be carefully washed, or scale insects and red spider may escape complete destruction. Any suitable insecticide may be used; for those who care to make their own specific one quarter of a pound of common brown soap to a gallon of warm, soft water forms a safe and efficient wash. Support the young shoots on the palm of the hand and carefully wash them, using a half-worn paint brush, and a stiffer brush for the main stems and branches. When the trees are quite dry, first tie the main branches to regulate the shape, then fasten the young wood of the present year's growth in position, taking care that each shoot is at least 4 inches from its neighbours. Ventilate the house to its fullest extent both day and night.

Apricots.—Root pruning and renovating the borders is as necessary for Apricots as for any other stone fruits. Most growers lift and rearrange the roots in a horizontal position the third autumn after planting. Light fibrous loam and old mortar rubble should form the bulk of the compost, with a sprinkling of bone-meal, wood-ash, and soot. Let the borders be thoroughly moistened before lifting the trees, otherwise the fibrous roots embedded in the dry soil may be broken. Trim the roots and rearrange them in the fresh loam, then make the soil firm and give sufficient water to settle it about the roots. Defer tying the branches to the trellis until the trees have settled finally.

Strawberries.—The continued wet weather has not been favourable to Strawberry plants intended for next year's forcing. Still, much may be done towards ripening the crowns by removing the plants to shallow frames, where protection may be given during times of heavy rain. Keep the pots free from weeds and remove all runners. Move the pots occasionally to prevent the roots growing through the drainage holes. Plenty of ventilation is essential both day and night; air may be admitted by tilting the lights, but in such a manner as to protect the plants from rains. In fine weather remove the lights entirely.

PLANTS UNDER GLASS.

By E. Harriss, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Euphorbia (Poinsettia) pulcherrima.—The bracts are developing on Poinsettias, and a drier atmosphere must be maintained. With the shortening days and less sunshine the roots are not absorbing so much moisture as hitherto, and the plants should be examined carefully before water is given them. When the bracts are fully expanded discontinue the use of stimulants. Ventilate the house with extra care, admitting a little air through the top ventilators during the night to ensure a dry atmosphere. A night temperature of about 50° is suitable.

Pelargonium.—Grow winter flowering Pelargoniums near the roof glass in a light, airy glass house. With care they will flower during the greater part of the winter. The roots require a fair amount of water, and this should be supplemented occasionally with some form of stimulant. Whenever the weather is favourable admit air freely, and use fire heat only to keep out frost.

Roman Hyacinths.—The bulbs of Roman Hyacinths which were potted early will soon be ready for removal from the bed of ashes in which the pots were plunged. Place them for the present in cold frames. When they have made sufficient roots, a batch may be introduced into a warm house and gently forced into flower. It is doubtful if crowns of retarded Lily of the Valley will be obtainable this season, and Roman Hyacinths will form a good substitute. Batches of bulbs may be potted at intervals to ensure a long supply of flowers.

Early Narcissus.—Bulbs of Paper white Narcissus which were potted early should be examined, and if well rooted they may be taken from the bed of ashes and placed in a cold frame. It is unwise to attempt to force Narcissi until the pots are full of roots; even then much fire heat is undesirable. They will develop their flowers freely in a moderately warm temperature, and the blooms will be much more useful when grown in this manner.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER** 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, OCTOBER 21—
Nat. Chrys. Soc. Floral Com. meet at Essex Hall, Essex Street, Strand. Exec. Com. meet., 35, Wellington Street, Covent Garden.

TUESDAY, OCTOBER 22—
Royal Hort. Soc. Coms. meet

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 48·1°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, October 16, 10 a.m.: Bar. 29.8, temp. 52°. Weather—Dull.

Green Manuring.

There can be no doubt but that if soil fertility is to be maintained in gardens and allotments green manuring will have to be practised much more generally than is at present the case.

It looked at one time as though the pig would enable many gardens to supply to the soil the necessary humus-containing manure; but the difficulty of obtaining pig-food is so great that many people can scarcely manage to keep a few where otherwise they would be willing to keep many.

Thus, the intensive cultivator must have resource to green-manuring, supplementing this system by the judicious use of artificials.

But even in the case of a green manure crop the choice is very limited, and indeed at the present time Rye is probably the only plant which can be sown for digging in in the spring. Fortunately, it is one of the best, if not the best, for this purpose. On light land it often proves far superior to Mustard—which latter crop it is, of course, too late to sow now. From our experience, indeed, in certain cases Mustard as a green manure crop is useless on light land, but before accepting this assertion as generally true it would be interesting to have the experience of others who have tried it. In spite of the fact that it may make an excellent stand when dug in in the autumn, on sandy hungry soils, it is apt to leave no impression on the crops sown in the succeeding spring. Nevertheless, there is the general belief which must be put to the credit of this crop that it helps in some obscure but potent way to clear the ground of soil-pests such as wireworm.

One great advantage of Rye is that it makes rapid growth early in the year, and is ready to dig in in time to admit of the planting of main-crop Potatos, but it must be remembered that if the digging in is late, light soils will not have had time to settle down, and hence not be suitable for the sowing of small-seeded crops. Needless to say, when the "straw" is dug in at about 15 inches in height, it should not be buried deeply: if just covered by the top spit of soil, that will be deep enough.

Another means of assisting in the maintenance of soil fertility which is not so generally known as it should be is by the application of potassic manures, of which the only one readily available at present is wood ash. Liberal dressings of wood ash are of the greatest assistance to most soils, and in particular its benefit will be shown on light soils in time of drought. For potash, by prolonging the season of growth, helps the plant to hold on its vegetative way when otherwise it would be tempted to bolt. Those who so often fail to prevent Spinach and Lettuce from bolting might well try the expedient of dressing liberally with wood ash the ground which is destined for these crops.

Yet another method of increasing fertility and improving the working of heavy, unkindly soils such as are met with in some parts of Sussex is by growing Lucerne. At the present time, however, this is out of the question.

If, as there is every reason to expect, the difficulty of obtaining supplies of natural manures goes on increasing, green-manuring will inevitably become a routine practice in the vegetable garden. For our part, we think that it should be so now, for its benefits are certain and the cost of the operations involved is not high. We have said nothing of the other Leguminous crops, such as Vetches and Lupins, which are suitable for this purpose partly because for them to be of use they must be sown earlier in the season, and partly because the supplies and price of seed tend to preclude them from use for the purpose of green-manuring.

Royal Horticultural Society. — The next meeting of the Committees of the Royal Horticultural Society will be held at the London Scottish Drill Hall, Buckingham Gate, Westminster, on Tuesday, the 22nd inst. At the 3 o'clock meeting of the Fellows Mr. ARTHUR W. SUTTON, J.P., will lecture on "The Great Value and Importance of Sowing in July and August for Producing an Additional Crop of Vegetables during the Autumn Months and thus adding to the National Food Supply." Mr. SUTTON'S address will be illustrated by lantern slides.

Horticultural Club.—The luncheon held by the Horticultural Club on Tuesday, the 8th inst., was attended by some forty members and friends. The Committee has decided to hold a luncheon at 2, Whitehall Court, on the occasion of the Royal Horticultural Society's fortnightly meeting, on November 5. The price of the luncheon, exclusive of wine, will be 3s. 6d. Those intending to be present are asked to notify the hon. secretary, Mr G. F. TINLEY, 41, Wellington Street, Strand.

Flowers in Season.—From Messrs. R. VEITCH AND SON we have received blooms of Nerine Bowdenii and the pale-coloured variety named pallida. The spikes of both were unusually vigorous, and were cut from plants growing in the open in their Exeter nursery.

Fruiting Barberries.—Mr. T. SMITH, Daisy Hill Nursery, Newry, has sent us a selection of fruiting Barberries. The forms of Berberis vulgaris, including asperma, also B. sinensis, are particularly beautiful, but much excelled by the fruits of Berberis virescens fructo coccinea, which, Mr. SMITH states, "excels all others of the family." To show how very variable Berberis virescens comes from seed, Mr. SMITH sends shoots in which the berries vary from bright red to black. In addition to the Barberries were sprays of Cotoneaster Franchettii, the coral-red fruits contrasting finely with the grey-backed foliage.

A Large Peach.—Mr. ALFRED T. GOODWIN, Roseholme, Maidstone, writes: "I have just gathered a Peach of the Salwey variety, weighing 15½ oz., and measuring 12½ inches in circumference. This season there were about 60 other fruits on the tree of Salwey, and some of these were included in the annual presentation made by the Fruiterers' Company to the Lord Mayor on Wednesday, the 9th inst. The 24 Salwey Peaches included in the gift weighed between 9 oz. and 10¾ oz. each. Have you any record of any Peach larger than my fruit of Dr. Hogg, weighing 25¾ oz., which I gathered in 1880?" We have no entry in our "Record" book of a Peach larger than Mr. GOODWIN'S fruit of Dr. Hogg variety, which was recorded in *Gard. Chron.*, August 27, 1881, p. 272.

Gift of Fruit to the Lord Mayor of London.—In accordance with an annual custom established many years ago, when the Lord Mayor of London surrendered his right to levy a toll on fruit brought into London, the Master, Wardens and Court of the Fruiterers' Company on the 9th inst. made a gift of fruit to Colonel Sir CHARLES HANSON, M.P., the retiring Lord Mayor. The present included Grapes, Pears, Strawberries, and Peaches. Alderman MOORE (Master of the Company), in responding to the toast given by the Lord Mayor at luncheon after the presentation, stated that as the outcome of a conference of horticulturists it was proposed to form a new Chamber of Horticulture. He hoped that this Chamber would weld together all the various associations in the country which were interested in the subject without interfering with their local work, and that, as a result of its efforts, the home-grower would have a better chance in the future.

Highbury Presented to the Nation by Mr. Austen Chamberlain.—At the meeting of the Birmingham City Council on Tuesday, October 15, the Lord Mayor moved a resolution of thanks to Mr. AUSTEN CHAMBERLAIN for his generous and public-spirited gift of Highbury, the residence of the late Mr. JOSEPH CHAMBERLAIN, as a permanent hospital for limbless and chronic orthopædic cases of Service or ex-Service men. Mr. CHAMBERLAIN wrote to the Lord Mayor: "It is not without regret that I break my connection with a house which was my home for more than thirty years, and around which so many memories, public and private, gather; but since it is not possible for me to make it my home any longer I believe that my father would have approved the purpose to which it is to be devoted."

War Items.—Mr. GEORGE S. MORGAN, second son of Mr. JOHN FORBES MORGAN, gardener at Holme Chase, Weybridge, joined the Royal Engineers as a private the day war broke out, was later promoted to sergeant, and subsequently received a commission. He won the Military

Medal and a bar to it the following week. He has also been awarded the Military Cross for bravery. Mr. Morgan started his career as a gardener, but later joined the staff of the Great Northern Railway.

—— Sergt. Horace Eli Freeman, who was killed in France on September 29, joined the Forces in 1914. Prior to enlistment he was a representative of Messrs. Dunns' Salisbury), in West Hants and the Isle of Wight. He was a man of fine physique, and possessed a genial and courteous manner which secured for him many friends both in the Army and civil life. He fell leading his platoon in a charge against the enemy. Before the war Sergt. Freeman was treasurer of St. Michael's Church, Bournemouth, in which town he resided. A brother N.C.O., in a letter to his parents, wrote: "We all feel that England has lost one of the finest men she ever sent to the Western Front."

— Kew men in many lands will hear with great regret of the death of Mr. Arnold Duley. When war broke out, Mr. Duley was gardener at the Haraks Estate of his Serene Highness the Grand Duke George of Russia, in the Crimea. After a long and, at times, perilous journey overland and in northern waters, he reached England in 1915. Joining the Somerset Light Infantry, he went with the seventh battalion to France, and was in much hard fighting. He had gained the Military Medal, before being taken prisoner in 1917. For a time Lance-Corporal Duley was in the Dulmen Prisoners' Camp, and in February, 1918, was sent to work in Belgium, where he died in hospital at Tournai on March 14. Mr. Duley entered Kew from Codicote Lodge Gardens, Welwyn, Hertfordshire, in March, 1906, and on completion of the two years' course was appointed foreman in the Cardiff Public Parks.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables in *Gardeners' Chronicle* for August 3, p. 42.)

(*Concluded from p.* 138.)

IRELAND, S.

Kerry. It is difficult to account for the smallness of the Apple and Pear crops this year.

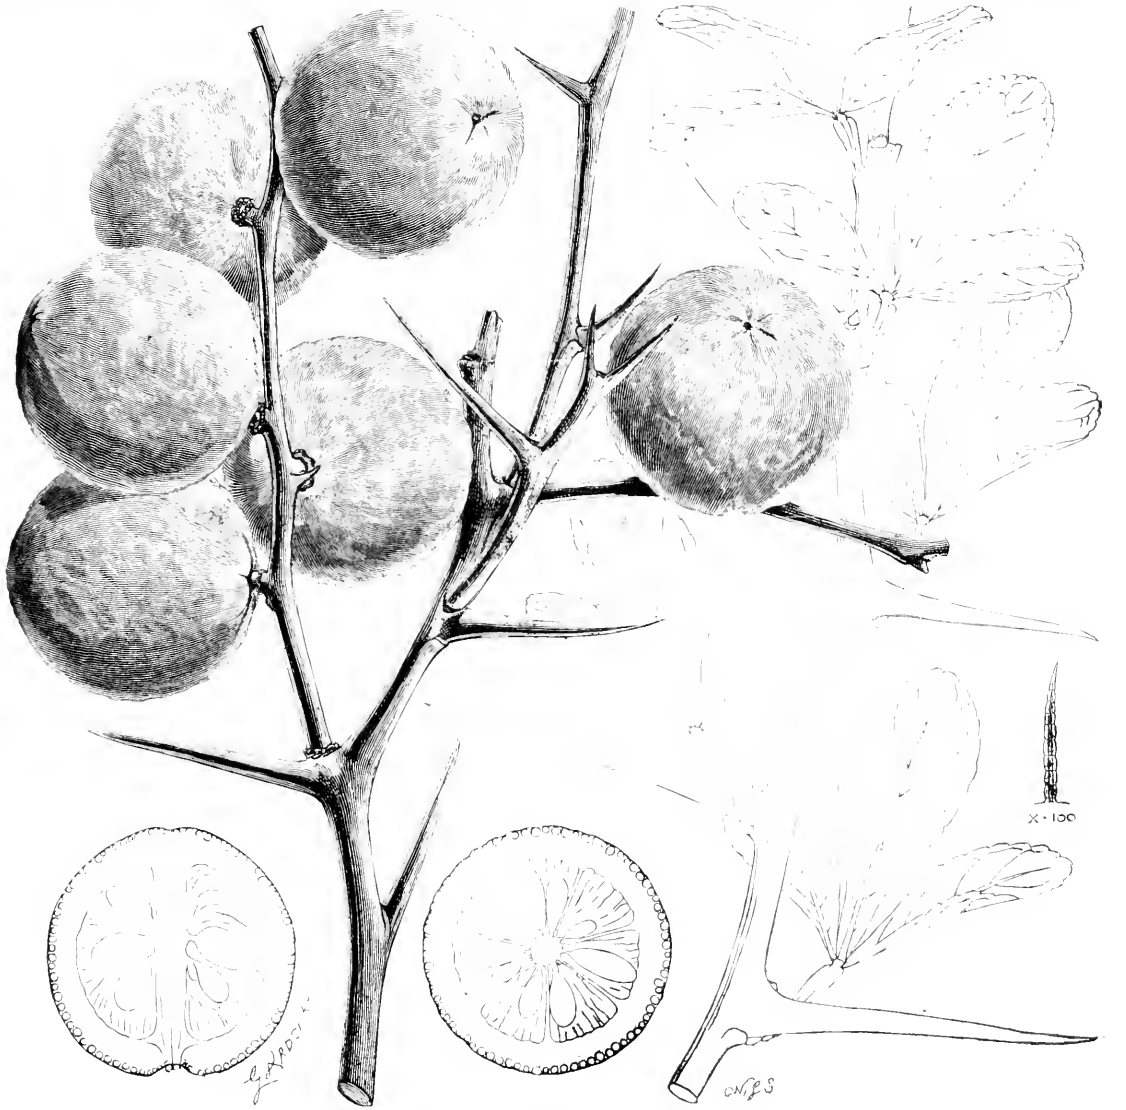

Fig. 62.—Fruits and foliage of Citrus trifoliata: a hardy orange.

(See p. 157.)

The trees flowered well and in good weather, and few insect pests troubled them, yet only a small proportion set any fruit. Young trees gave better crops than old ones. Soft fruits bore good crops, especially Red and Black Currants. Strawberries yielded a light crop owing to a period of drought after the flowers had set. The only serious pest has been the caterpillar of the Gooseberry Saw Fly. *Charles W. Bennett, Muckross Abbey Gardens, Killarney.*

KILDARE.—The crops here were very poor: Strawberries and Gooseberries were a complete failure. Red spider and aphis are most troublesome, in spite of spraying. The soil varies from a heavy, retentive clay over limestone, to a sandy loam. *Frederick Streeter, Straffan House Gardens, Straffan Station.*

KILKENNY.—The scarcity of fruit in this district is the result of the extremely mild winter. All kinds of fruit came too early into growth and flower, with the result that the cold snap in April did the maximum amount of damage. Apricots flowered at the end of February, but these, being covered at night, have carried a splendid crop. Strawberries on south borders began to flower in March, and in some cases three lots of flowers were blackened successively. Strawberries on north borders, on the contrary, were very good indeed. Plums varied considerably, some trees being laden with fruits, whilst others were quite bare. These, however, in many cases, were over-cropped last season, when, owing to scarcity of labour, thinning could not be carried out. With regard to Apples, generally speaking early varieties were much better than late ones. Such dessert varieties as Irish Peach, Worcester Pearmain, and James Grieve carried good crops, whilst Cox's Orange, Chas. Ross, and Allington Pippin were failures. Amongst cooking varieties Lord Grosvenor, Grenadier, Yorkshire Beauty, Lane's Prince Albert, and Tower of Glammis were very good. Figs outdoors are the best crop we have had for some years. *T. E. Tomalin, Bessborough, Piltown.*

KING'S COUNTY.—The frost and cold winds during the month of May caused considerable damage to all large fruit trees. The heavy hailstorms during the second week of July damaged some of the Apple and Pear fruits; in fact, in some parts of the country the fruits were very deeply cut with hailstones. Aphis was very prevalent during the dry weather. *E. Clarke, Clare mount, Garry Castle, Banagher.*

LIMERICK.—The Apple crop in this district did not fulfil the expectations that were held during the blossoming period. Owing to frost and cold showers of hail, there was a poor set of fruit. Some varieties of Apples carried good crops, while others were very thin, but of good quality. The blossom wilt seems to be spreading in spite of cutting and burning all diseased shoots. Pears were a failure; only a few scattered fruits of poor quality developed. Plum trees bore a nice, even crop, of good quality, but Damsons, although covered with flower, failed to set any fruit. Small fruits gave remarkably heavy crops, Gooseberry bushes in particular being weighted to the ground with fruit. Strawberries were very large on young plantations, and two-year-old plants bore an abundance of fruit of small size. The soil here is heavy loam over limestone rock. *Harry Nixon, Rockbarton Gardens, Kilmallock.*

QUEEN'S COUNTY.—Apples were very promising in the early part of the season; nearly every variety had a profusion of bloom, but most of it dropped off. This was probably due to the unusual dryness of the season; there was no frost during the period they were in bloom. All small fruits were very good. *G. McGlashan, Abbey Leix Gardens.*

WATERFORD.—All fruits, with the exception of Gooseberries, Raspberries, and Black Currants, were very poor and scarce. There were practically no Apples, Pears, or Plums, but Gooseberries, Raspberries, and Black Currants gave abundant crops of good fruit. The soil is rather light, on a clay subsoil. *D. Crombie Curraghmore Gardens, Portlaw.*

CHANNEL ISLANDS

JERSEY.—The fruit crops in Jersey this year have been very poor. This is locally attributed partly to the damage caused by a blizzard last season, and partly to the cutting east wind this year when the trees were in bloom. *T. Sharman, The Imperial Nursery, St. Heliers.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Augmenting the Fuel Supply for Glasshouses.—Two items of fuel not mentioned, I think, in your leading article on this subject in the issue for September 28 [see *Gard. Chron.*, July 6, p. 6.—EDS.] are worth noting, namely, ashes and cinders. On many estates there is to be found in some out-of-the-way corner a heap of ashes and clinkers which has been collected in pre-war days. The heap should be overhauled and sifted—when, generally, the result will be astonishing; for in those days of plenty the separating of odd pieces of fuel (coal or coke) and cinders was not done very thoroughly. Such siftings, where procurable, will be, in the coming winter, a substantial help to the allotted amount of fuel. Ashes, too, used wet, will effect a saving of better fuel, and they could be used on mild and sunny days. The saving is effected by feeding the fire with the wet ashes occasionally instead of coal or coke, while, if it is not necessary to keep the fire burning, it can be banked with sufficient wet ashes to last for several hours without attention. On re-visiting the furnace it will be found that the ashes have caked together and burnt through, giving a nice body of fire—which in turn can again be fed with ashes or the better fuel as the occasion demands. *C. Turner.*

Apples in Public Parks (p. 142).—Mr. Molyneux has done well to draw attention to the subject of planting fruit trees in public parks. I have advocated such planting for many years, but have been met with the objection that the fruit would be stolen. I maintain that the public has the same respect for fruit as it has for flowers and shrubs. The educational effect on the people of seeing fruit in the public gardens, enabling them to note the best system of planting, pruning, spraying and training, would be valuable, and they could note the best varieties to plant in their locality. Mr. Stevenson deserves congratulations on his bold project. *"Pomo."*

"Rogues" among Potatos.—This case of a Potato "sport," or bud variation, as Darwin terms it, cannot be so readily disposed of as Mr. Arthur W. Sutton appears to think. Because M. Labergerie made a mistake, it does not follow that I also have. Indeed, I know that the tuber which "sported" was a Sharpe's Victor, planted, under my own supervision, in the little vegetable plot, in my garden, by one of my children. I sought advice from the best people, Messrs. Sutton and Sons, who welcomed the enquiry, and said, in a letter of July 24, 1906, signed by Mr. Arthur W. Sutton: "I do not think there need be any difficulty in stating what the variety is, but it might be necessary to plant the tubers in our Trial Grounds next year before coming to a final decision." All the subsequent letters are signed by the firm. In the September following they wrote: "The tubers shall be carefully planted in our experimental grounds next season, and we have no doubt we shall be able to identify the variety for you." In 1907 it could not be named, the growth being weak, it was stated, so in November Imperator and Snowdrop were mentioned for a further trial, saying, "We are much obliged to you for letting us test this Potato." The next month Up-to-Date was added as likely. It was found, in 1908, to be neither. In September that year M. Labergerie was referred to, and I was most kindly given a copy of a brochure printed as a result of a Potato demonstration held at Reading in the autumn of 1906. M. Labergerie's Potato and the Blue Giant were also mentioned. In October, 1908, they wrote: "You may rely upon our planting your Potato next year in our trial grounds. We quite hope it may then prove possible to clear the matter up." In 1909 it remained unnamed, and I wrote to Kew, with the result mentioned in my previous letter, viz., that the Potato did "sport." I wish fully to acknowledge Messrs. Sutton and Sons' great patience and courtesy. I am quite unable to agree with Mr. Arthur W. Sutton's view when he says: "It is quite clear from the instances that Darwin gives that the only kind of bud-mutation he had in mind was that which gave a difference in the colour of the skin of the tuber." Words, in my opinion, could not be clearer than Darwin uses to express the statement that the Potato produces quite new varieties from the tuber. "A single bud or eye," he writes, "sometimes varies and produces a new variety," and of the red variety of Kemp's Potato, "being found a more productive variety": again, in Chapter IX., page 423: "It is an argument of the greatest weight that when varieties are produced by simple bud-variation, they frequently present quite new characters." The cases he quotes are not from his own observation, but from that of others, and it is much easier to notice a change in colour than in some other respects. My letter in 1916 referred to by Mr. Sutton was after the Potato had improved, when I suggested its trial as a marketable sort. I have written these letters to show that "rogues" among Potatos can no longer be treated on the principle of "Give a dog a bad name and hang him." *S. Jackson.*

—— I much appreciate the opportunity you have given me of seeing the letter from Mr. Jackson printed above. When writing the letter which you published on October 5 I had only time to turn up the letters that had passed since the autumn of 1916, but I have now traced all the others to which Mr. Jackson refers, and have verified the quotations he gives as far back as July 24, 1906. I have also been able to turn up particulars of a previous correspondence in 1898, when Mr. Jackson wrote with regard to a Potato he found growing amongst his crop of Satisfaction, and which he thought was a sport, but which we were able to identify as the then well-known white form of Beauty of Hebron, and differing only from Beauty of Hebron in the colour of the skin. In Mr. Jackson's letter which appeared on September 21 he admitted that his "new Potato" was not an advance on Sharpe's Victor, the sort from which he believed it had originated by bud-variation, and the fact of the Potato being of little, if any commercial value was fully confirmed by the repeated trials made in the seasons of 1907, 1908 and 1909, for in each of these years the constitution of the Potato was so poor and weak, that, writing on September 18, 1909, we said that any further attempt to identify the Potato would scarcely be worth the time or trouble spent. The only question of any interest, therefore, is whether the Potato Mr. Jackson found growing amongst the crop of Sharpe's Victor planted by one of his children was, or was not, a distinct variety which has arisen by bud-variation. To strengthen his case Mr. Jackson mentions that it had been repeatedly planted in our Trial Grounds without our having identified it. Mr. Jackson is welcome to attach such importance as he thinks fit to this undisputed fact, but it by no means proves the Potato to have been a sport from Sharpe's Victor. In the great majority of cases identification would be quite easy, although we all know that the soil and climate where Potatos have been grown the previous year so greatly affect the habit of the plant that two samples of one and the same Potato from different sources may differ so much when planted alongside as to be hardly recognisable for the same variety. It is quite possible that in the stress of work involved in examining many hundreds of new seedlings and trial rows of commercial varieties, and visiting and inspecting crops for seed in Scotland and England, the fact that an unpromising Potato had been sent for the purpose of naming might have been overlooked until too late. However this may be, if it was impossible to identify the Potato, there is nothing in what Mr. Jackson tells us which in any way shows it to have arisen by bud-variation. To prove this it would have been necessary in the first instance to have evidence that in the previous year the Sharpe's Victor grown by Mr. Jackson was absolutely true to type, and that no Potatos had been grown on the same land the year before. Secondly, whereas a stray tuber of another variety might have been introduced that year in the manure, it would have been necessary for Mr. Jackson to have ascertained that the tubers he kept and planted the following year were actually produced upon, i.e., attached to the haulm of, a true plant of Sharpe's Victor. Thirdly, that the ground where Mr. Jackson's child planted the tubers the following year had not grown Potatos recently. Fourthly, that by no possible accident had any tubers of another variety been mixed with those his child planted; and fifthly, that

no "crats" or even Potato parings could have found their way into the manure which presumably was applied to the ground. There is always the possibility of some discarded "seedling" finding its way into any stock of Potatos. I still maintain that all the quotations from Darwin which Mr. Jackson gives refer exclusively to colour variation, and the fact that Darwin expressed the opinion that in one case the Potato which showed variation in colour was more productive proves nothing, for this may have been due to nothing more than a change of soil. I hope to deal more fully with the question of bud-variation in a paper I have been asked to read at the forthcoming Conference at Ormskirk on the 30th inst. *Arthur W. Sutton.*

Women's Farm and Garden Union (see p. 151).—The Women's Farm and Garden Union was founded so long ago as 1899, and is in no sense a new war society. It was because of our long experience as to the training and employment of women on the land, in pre-war days, that we were able to do so much, at the outset, in adapting training for the war conditions. The Women's National Land Service Corps is a war branch of the Union. Your notice infers that the Corps was the original body, which is not the case. *S. L. Chamberlain, Editor of the "Monthly Leaflet".*

Polyantha Rose Jessie (see p. 136).—Mr. J. P. Carlisle's interesting note brings memories to me of this beautiful Rose. A few years ago, at Newstead Abbey, Byron's old home—the variety Jessie was planted freely and gave great satisfaction, the plants being a beautiful picture from early summer until October. The soil was very sandy and the garden exceptionally well sheltered. Here, on the Yorkshire Wolds, subject to much wind, Jessie is miserable, whilst the variety Orleans succeeds splendidly. *Sidney Legg, Winter Prang Gardens, York.*

—— The defect of defoliation in Polyantha Rose Jessie referred to by J. P. Carlisle on p. 156 does not obtain with our plant of this variety. The second defect of double flowers is, in my opinion, the result of spotting, as, since care has been taken in the selection of buds no plant with this defect has appeared in our stock. A few plants that produced double flowers have been tried in many situations and soils without success, all the blooms fading to open. *D. Prain.*

SOCIETIES.

STRATFORD-ON-AVON ALLOTMENT HOLDERS'.

At present lack of space did this Society has a roll of nearly 400 members, and held a first-rate two days' exhibition of vegetables in the Corn Exchange at the end of September. The produce was sold during the closing hours of the show, and realised £22 for local charities.

In the open classes H. B. Lyle, Esq., gardener, Mr. A. E. Moss, Bishey Manor, won 1st prize for a collection of twelve kinds of vegetables. Mr. G. Eveleigh and Mr. Nicholls were also successful prize-winners, and Mr. C. Smith had the two-dozen exhibit of Potatos, judged by weight, his twelve tubers weighing 11 lbs. 12 oz.

FAULKBOURNE ALLOTMENT AND COTTAGE GARDEN.

September 25.—The second annual vegetable show of this Society was held in the grounds of Faulkbourne Hall, the residence of the president of the Society, C. W. Parker, Esq.

The show was a great success, the exhibits and especially Potatos were of splendid quality. Messrs. Beard & Hall and S. Kerry supplied the members with 3 sets of Tremedeus Potato for a cropping competition. The 1st prize was won by Mr. F. Challis with a crop of 21 lbs.

Publications Received. *School and Home Gardening.* By Kary C. Davis, Ph.D. (Philadelphia and London: J. B. Lippincott Co.). Price 4s. 6d. net.—*A Monograph of the British Lichens.* Part I., second edition. By Annie L. Smith, F.L.S. (London: Printed by order of the Trustees of the British Museum, Cromwell Road, London, S.W. 7.) Price 30s.

CROPS AND STOCK ON THE HOME FARM.

Wheat Stubbles for Oats.

Where a satisfactory crop of Wheat was produced and the field is free from Couch or other obnoxious weeds, a satisfactory crop of spring-sown Oats should follow with a minimum of expense for labour. Where the soil is heavy and difficult to work in February or early in March, as in my case, it is advisable to sow the Oats broadcast on a "stale fallow." To get the land into this desirable condition it should be carefully ploughed, burying any weeds and the whole of the stubble during October or November. The winter rains and frost will pulverise the surface soil, rendering it quite friable in February or March, when an early start can be made with sowing. Oats sown under these conditions generally succeed much better than those sown later, and certainly such sowing does not involve so much labour is when spring ploughing is practised.

Couch Grass.

The almost continuous rains for the past three weeks have checked the killing of Couch Grass on arable fields. Instead of attempting to clean stubble now by scarifying I advise the early ploughing of such plots, putting on the skim coulters to ensure complete burial of all grass. Where this is neglected, as is too often the case when ploughing is done without the use of skim coulters, it is surprising how quickly the grass grows between the furrows, whereas, where skim coulters are efficiently used, the surface is completely buried and the grass and weeds die. If the Couch does not also die it remains dormant, having no foliage, and if suitable weather is experienced in February or March the land can be cross-ploughed to remove the soil from the Couch roots with a good prospect of eliminating much of the weed. *T. Middleton.*

The Agricultural Outlook.

Late reports received by the Crop Reporters of the Board of Agriculture and Fisheries on agricultural conditions in England and Wales show that September was exceptionally a wet month. Over 4 in. of rain had been carried by the first week in the month, nearly three-quarters of the total average fall for October, and this fall exceeded 5 in. in many parts of the north and west. The crop of Hops has been harvested during most unfavourable weather, and is good to a fair average. In Lincolnshire a certain proportion of the main crop of Potatos has been lifted, but elsewhere little has been done apart from harvesting the early and second earlies, owing to the protracted corn harvest and wet weather. Very little disease is reported, and prospects for a yield about 5 per cent. above the average are still maintained.

Roots have grown well during the wet weather, and promise to be somewhat improved, especially those of Turnips and Swedes, although the are still of small size, and fields are often patchy. Their yield is expected to be about 91 per cent. of the normal, while that of Mangolds, which would have done better with more warmth, is expected to be 90 per cent. of the average.

Turnips grown for seed in the eastern counties have generally yielded satisfactorily, but the quality of much of the Mangold seed has been affected by the wet, and prospects for red Clover are not satisfactory.

Autumn cultivations is, upon the whole, backward, although there are districts—those where much of the corn was secured during August—where it is often considered to be forward. But the very wet weather in most parts of the country prevented much work of this character, even where the corn crops have been cleared. Much plough-ing has been done by tractors, which are of great assistance.

Seeds are rather variable, but in many places there is a good bottom plant, and they are satisfactory on a whole, though often patchy. Some harm is being done by the corn stooks remaining so long in the fields.

Pastures generally have plenty of grass, but from all parts it is reported that its quality or feeding value is poor, owing to the excessive rains.

Obituary.

John Puttock. One of the oldest inhabitants of Kings on-on-Thames, Mr. John Puttock, died at his residence, 28, King's Road, on October 5, aged 84 years. He was born at Bramley, Surrey, and about 60 years ago entered the service of Messrs. Thomas Jackson and Son, nurserymen, of Kingston and Kingston Hill. In 1865 he became head of the glass department, and during the following 25 years he was a very successful exhibitor of the firm's productions at Regent's Park, the Crystal Palace, South Kensington, Manchester, Nottingham, Preston, Birmingham, Southampton, Brighton, Tunbridge Wells, and at other important flower shows, and his services were in frequent request as a judge. On the dissolution of the firm of Messrs. Thomas Jackson and Son in 1886 he took over the goodwill of the business in partnership with the late Mr. G. H. Shepherd. In January, 1902, this partnership was dissolved, and the late Mr. Puttock continued the business on his own account until 1909, when he retired. He was one of the founders of the Kingston and Surbiton Horticultural Society some 57 years ago, and about 15 years later was the prime mover in the formation of the Kingston and Surbiton Chrysanthemum Society. His local interests were not confined to horticulture, for he was one of the founders, and for 14 years joint secretary, of the Mid-Surrey Cricket Club (now Kingston Town), which commenced with twenty members and, largely due to his energy and geniality, increased to over 300 members. Inexorable time compelled him to give up active participation in cricket, so he took up the game of bowls with such success that in his 70th year he won the Kingston on Thames Club's championship. His tall, erect figure was well known in the neighbourhood of Kingston, and his genial disposition made him exceedingly popular. His funeral, at Kingston Cemetery, on October 10, was largely attended by the townspeople, and there were many floral tributes. He leaves four sons and two daughters; his wife predeceased him in 1900.

William F. Dreer. It is with great regret we learn from an American correspondent of the death of Mr. William F. Dreer, of Philadelphia. Death took place on September 8, at Woodstock, Vermont. Deceased was born on November 11, 1849, and educated for the purpose of joining his father in the seed business. When eighteen years of age he went to Germany to study various branches of the seed trade, and subsequently continued his studies in France. Upon his return home he took an active part in the seed and plant industry at Philadelphia, and on his father's death in 1873 he took full charge of the business founded by Henry A. Dreer in 1836. He was greatly liked and widely known, and continued in business until about two years ago, when he was stricken with Bright's disease, which eventually caused his death.

REPLY.

Plants of the Druids.

In reply to the query by *Welsh Reader* on p. 94, he will find several plants that were associated with Druidic rites mentioned in R. Folkard's *Plant Lore, Legends, etc.*, 2nd edit., 1892, from which work I have made the following extracts:—

Apple Tree. The Druids highly reverenced the Apple tree, partly on account of its fruit, but chiefly because they believed that the Mistletoe thrived on it and the Oak only. In consequence of its reputed sanctity, therefore, the Apple was largely cultivated by the early Britons, and Glastonbury was known as the "Apple Orchard," from the quantity of fruit grown there previous to the Roman invasion. The Druids were wont to cut their divining rods from the Apple tree.

Belinuncia. Under the appellation of Kid, or Cridiven the Druids worshipped the moon, which was believed to exercise a peculiar influence on storms, diseases, and certain plants. They consecrated a herb to her, called Belinuncia, in the poisonous sap of which they dipped their arrows, to render them as deadly as those malignant rays

of the moon which were deemed to shed both death and madness upon men.

Mistleto.—In Druidic times the Mistleto was regarded as a divine gift of peculiar sanctity, only to be gathered with befitting ceremonies, on the sixth day, or at latest on the sixth night, of the sixth moon after the winter solstice, when their year commenced. . . . As the Druids attributed to the Mistleto marvellous curative properties, they placed it in water, and distributed this water to those who deserved it to act as a charm against the spells of witches and sorcerers. If any portion of this plant came in contact with the earth, it was considered as ominous of some impending national disaster. The practice of decorating dwellings with Mistleto and Holly is undoubtedly of Druidic origin.

Oak.—The sacred Oak was thought to possess certain magical properties in invoking the spirit of prophecy; hence we find the altars of the Druids were often erected beneath some venerated Oak tree in the sombre recesses of the sacred grove. . . . The ancient Britons dedicated the Oak to Taranis, their god of thunder, and the Celts, under the form of an Oak, are by some authorities stated to have worshipped Baal, the god of fire. . . . The festival of Baal was kept at Yule (Christmas), and on the anniversary the Druids are said to have ordained that every fire should be extinguished, and then relighted with the sacred fire, which, in their sacerdotal character, they always kept burning. In this rite, it is supposed, may be traced the origin of the Yule log, the kindling of which, at Christmas time, is still kept up in England.

Rowan Tree, or Mountain Ash.—The Rowan is generally considered to have been one of the sacred trees of the Druids. Stumps of the Mountain Ash have frequently been found within or near the circle of a Druid temple, thus proving that the tree must have been an object of great veneration with the Druids, who doubtless practised their sacred rites beneath its shade. This connection of the tree with Druidic customs affords some explanation of the many superstitious ideas appertaining to the Mountain Ash which are still extant. Lightfoot tells us that the Rowan tree is discovered in the Druidic circles of North Britain more frequently than any other, and that even now pieces of it are carried about by superstitious people as charms to protect them from witchcraft.

Samolus.—The Samolus was a plant held in high esteem by the Druids. It grew in damp places, and was only to be gathered by a person fasting—without looking behind him—and with his left hand. It was laid in troughs and cisterns where cattle drank, and when bruised was a cure for various distempers.

Selago.—Selago was the name of a herb held in great repute by the Druids, and intimately connected with some of their mysterious rites. It was known as the Golden Herb, or Cloth of Gold, and was reputed to confer the power of understanding the language of birds and beasts. It is variously supposed to have been the Club Moss (Lycopodium Selago), Camphorosma monspeliacum, or a kind of Hedge Hyssop, which used in olden times to be called Gratiola and Dei Gratia, and was regarded as a charm as well as a medicine.

Trefoil.—The Druids thought highly of the Trefoil because its leaf symbolised the three departments of nature—the earth, the sea, and the heaven.

Vervain, or Verbana.—The Druids, both in Gaul and in Britain, regarded the Vervain with the same veneration as the Hindus do the Kusa, or Tulasi, and, like the Magi of the East, they offered sacrifices to the earth before they cut the plant. This ceremony took place in the spring, at about the rising of the Great Dog Star, so that neither the sun nor moon would be at that time above the earth to see the sacred herb cut. It was to be dug up with an iron instrument, and to be waved aloft in the air, the left hand only being used. It was also ordained by the Druidical priests, for those who collected it, that before they take up the herb they bestow upon the ground where it groweth honey with the combs, in token of satisfaction and amends for the wrong and violence done in depriving her of so holy a herb. The leaves, stalks, and flowers were dried separately in the shade, and were used for the bites of serpents infused in wine. Another account states that the Druidesses held Vervain in as great veneration as the Druids did the Mistleto. They were never permitted to touch it. It was to be gathered at midnight, at the full of the moon. *Wm. Wade, Hyndland, Glasgow.*

ENQUIRY.

OLD GARDENING BOOK.

I BELIEVE there is a book, published in the eighteenth century, describing the garden at Hanworth Place, Middlesex, belonging to Sir — Chambers, and subsequently to Lord Vere. I do not know the title of the book, but should be very glad if any reader could give me any particulars. *O. B.*

TRADE NOTE.

MR. GEORGE PAUL'S GOLDEN WEDDING.

To the congratulations already extended to Mr. and Mrs. George Paul, of Cheshunt, on the occasion of their golden wedding on Monday, the 7th inst., we add our own. As a raiser of Roses and an introducer and cultivator of new Lilacs, and other hardy shrubs, Mr. George Paul occupies a high place in the world of horticulture. Many are the friendships he has made and held during a long and busy life; in short, his genial good nature is as well known and highly appreciated as his eminence as a horticulturist. Mr. Paul was chairman of the Hertfordshire County Council in 1908, and has been a Justice of the Peace for that county ever since. We trust that Mr. and Mrs. Paul may long be spared to enjoy health and strength and happiness.

ANSWERS TO CORRESPONDENTS.

ADDRESS. *Correspondent.* The secretary of the American Rose Society is Mr. E. A. White, Ithaca, New York, and the editor of the American Rose Society's Annual is Mr. Horace McFarland, Harrisburg, Pa., U.S.A.

CONTROLLED PRICES FOR APPLES: *H. J. B.* "Jam" Apples are those capable of passing through a ring 2 inches in diameter, and these may be sold only to a licensed jam manufacturer or to a salesman who undertakes to resell them to a licensed jam manufacturer. Cox's Orange Pippin does not come under "jam" Apples but Ribston Pippin does. The controlled prices for Apples other than "jam" Apples were given in *Gard. Chron.*, Sept. 28, p. 134. So far as we are aware the prices of dessert Pears are not controlled.

DISPASSED POTATO. *G. B. B.* The only disease found in the tuber received is the common Potato disease (Phytophthora infestans).

EMPLOYMENT AT KEW. *A. B. C.* Write to The Curator, Royal Gardens, Kew, Surrey, for particulars and form of application for employment. It will save time if you send a brief account of your experience and state what gardens you have been employed in, age and height.

GARDENER'S NOTICE TO LEAVE: *Legal.* It is customary for a head gardener to give or receive a month's notice to conclude service. In the case of an undergardener a week's notice is sufficient on either side. Local conditions may affect the case of a head gardener, i.e., he may or may not be considered a domestic servant, therefore your best plan is to consult a solicitor.

MEALY BUG ON NERINES: *Perplexed.* When mealy bug infests the roots of plants, as in the case of your Nerines, the best method of effecting a clearance of the pest is to turn the plants out of their pots and carefully remove all the soil from the roots. The soil must be burnt to prevent the distribution of the pest, and pots and staging must be thoroughly cleansed. Wash the roots and bulbs in warm and slightly soapy water until every trace of infestation has been removed, taking particular care that the base and neck of each bulb are thoroughly cleaned. When the plants are sufficiently dry for the purpose, repot them in clean compost and use clean pots. Watch the plants carefully, so that any reappearance of the pest may be observed and immediately dealt with by the use of a small brush and an insecticide.

NAMES OF FRUITS: *Rex.* Gravenstein.—*J. P.* Yorkshire Greening.—*J. M. F.* 1, Hoary Morning; 2, Mank's Codlin; 3, Lane's Prince Albert; 5, Bramley's Seedling; 6, Warner's King; 7, probably Chelmsford Wonder; 8, Newton Wonder; 9, King of the Pippins; 4, next week.—*J. O.* 1, Tom Putt; 2, Blue Pearmain; 3, not recognised, probably a local seedling; 4, Hollandbury; 5, Warner's King.

NAMES OF PLANTS: *Daisy.* 1, Cistus monspeliensis; 2, Cassinia fulvida, also known as Diplopappus chrysophyllus; 3, Berberis stenophylla; 4, Salvia azurea; 5, Echinops Ritro var. ruthenicus; 6, Caryopteris Mastacanthus.—*Rex.* The trailing plant is Tropaeolum speciosum; the shrub, Leycesteria formosa.—*Correspondent.* 1, Cardamine sp.; 2, Artemisia lactiflora; 3, Campanula pusilla; 4, Potentilla nepalensis Willmottiae; 5, Helenium autumnale; 6, Phygelius capensis.

SCALE INSECTS ON PEACH TREE: *G. E. T.* In addition to the suggested treatment of the soil, which is likely to produce good results, the trees should be carefully cleansed, as the "brown spots at the bases of the shoots" are scale insects (Lecanium persicae). Spraying the trees, while dormant, and also the walls, with paraffin emulsion or caustic alkali wash is recommended. The paraffin emulsion is made by dissolving 1½ lb. of soft soap in a gallon of boiling water and while still very hot adding 1 gallon of White Rose paraffin; churn the mixture vigorously to obtain an effective emulsion, and gradually add nine more gallons of hot water. On page 159 of the present issue a method of cleansing scale-infested Peach trees under glass is described; it entails more labour but is probably a more effective method than spraying.

SHOT-HOLE FUNGUS ON PEACH LEAVES: *G. B.* The fungous disease which produces the circular holes in Peach leaves is Cercospora circumscissa—the Shot-Hole Fungus. Spray affected trees with an ammoniacal solution of copper carbonate as soon as the leaves expand in Spring and again at intervals. Gather and burn all fallen leaves. One authority recommends spraying with lime-sulphur mixture when the leaves are expanding. This is made by placing 4 lbs. of good quicklime in a barrel, and pouring half a gallon of water on it to start the slaking process; then add 4 lbs. of powdered sulphur, gradually adding more water, and stirring the mixture to prevent caking at the bottom of the barrel, until the lime has been worked into a paste. When the boiling, due to the slaking of the lime, ceases, add sufficient water to make 25 gallons of the mixture, which should be strained previous to use and kept stirred during the process of spraying.

TREATMENT OF OLD ESPALIER PEAR TREES: *D. T.* Take out a trench along one side of the row, fairly close to the trees, and from this starting-point work under the trees and remove a large amount of the marly chalk subsoil. Cut back all stray roots pointing downwards and then fill in with fibrous loam and make all firm. Next year deal with the other side of the row in like manner. Cut out all dead and decaying wood at the end of December or in January, spray the trees with caustic alkali wash.

TOMATOS FOR MARKET SUPPLIES: *T.* Good varieties of Tomatos to cultivate for supplying the market with fruits are Kondine Red, Merivale, Sunrise, and Bide's Recruit.

VOLKAMERIA: *J. W. P.* Volkameria is now sunk under Clerodendron. If you will send us a flowering specimen we will do our best to name the species.

THE LOSS OF THE CLEMATIS IN GARDENS.

BEFORE the Royal Horticultural Society and under its auspices, Mr. Jackman gave a lecture on "Fashions as to the Clematis," in which he supported the practice of grafting the Clematis, which has already cleared the gardens of Europe of the most beautiful of the climbers of the Northern world. In that lecture there was no word said as to the Clematises of Japan and China on their native roots, either in nature or cultivation.

In clearing up this question, the first thing to do is to state a few facts about which there can be no dispute among any who are interested. The first is the extraordinary beauty of the plants. No conservatory or greenhouse in Europe shelters any plant so graceful in habit or so fine in colour of flowers. Added to this is the precious quality of hardiness and power to resist the rainstorms of our Isles. I have grown every obtainable kind in various positions, and never lost a plant from cold. The past summer, so wet day after day in July that my Roses became bags of ugly mould, and even native plants were sickened by the rain day and night, the large Clematises, on their natural roots, suffered not the slightest injury from the storms.

The Loss

The next fact, of which there can be no doubt, is that the gardens of Britain and of France have been robbed of the most beautiful race of climbers of the Northern world. Large gardens, with every advantage of site, soil, and air, are quite bare of them. It is not only in our country this loss has arisen through mistaken ways of increasing the plants. It is so everywhere in France, where we may see in the great nurseries at Orleans and Angers masses of the finest Clematises huddled together in pots, but never a plant on its natural roots. If one asks any question as to the diseases of the plants, only guesses are given. The loss to the trade is great. To suppose that clever propagators could not increase these hardy climbers in the natural way is absurd. The final test of the practice is not in the nursery, but in the grounds of the buyers of the plants. Any practice of increase which drives plants out of general cultivation is a loss to the trade as well as to the planter. From experiments carried on for many years here I have proved that the cause of the loss is the unnatural practice of grafting these plants.

Grafting, Not the Only Cause of Loss

After the grafting, a mistake is made in setting the plants out fully exposed to the sun. The nature of the Clematis in the wild state is to run over bushes and copses, as one may see on the shores of Northern Africa. So if we plant beneath a bush a little shade is afforded, and though the growth is not so free as when the plants are set apart, the life of the plant is longer and the effect is more beautiful. Lastly, more dangerous than the worms and the grubs are slugs, which bark the fragile stems as far up as they can get, and that means the death of the shoot in summer, but not the death of the plant of course on its own roots. Lawn mower, hoe, or rake may smash the delicate stems if the plants are set out singly, especially if grafted, as the union of the hardy variety and the wild stock used is often fragile. Others on the plant on its natural roots never die. Only in sunny days partial losses are by shoots dying off, but other on its own roots do not lose the plant.

The next is the story of my planting and success here by following a completely different way from the common one. It at first struck me that the grafting of plants of different species was not always justified in results. In the nursery practice the rule is to work the Clematis of Japan on the toughest and most vigorous climber of our chalk hills, a wholly different plant and from a different country, and, therefore, there might be a cause of death through the sap arising at different times in the two plants in the spring of the year. The next thing was to test the matter by planting not an easy matter, as in every nursery there were only the grafted plants and like so many others I lost many. At the same time there was a demand in many places that the Indian Mountain Clematis and other wild kinds which are grown on their natural roots are vigorous climbers. The stool ground at which the old nurserymen layered their plants was done away with in favour of the new way of boxing stocks by the thousand with no thought as to the result to the planter.

In only one nursery in France that of the late Ferdinand Lamin, of Bourg la Reine, Seine, a much trusted French nurserymen did I find the stools of Clematis, the little plants simply layered into pots around in the open air. I had many of these, and never failed with them.

At home I often bought batches of plants of the best kinds from nurseries of good repute. On examination they were all found to be grafted on *C. Vitalba* of the Wiltshire and Surrey hills. The roots of every plant were washed out, and the dark roots of the native kind an ugly mass, with above it a few roots of the true plants striving to make way, were found. The latter were carefully saved for planting, and the former with the stock, cut off and thrown away.

I have planted the very finest kinds in every sort of position, some in the hedgerow, round an orchard, in open ground, and in close shade of trees and shrubs, and in spite of the surgical operation of cutting off the stock described above, have had success in all. With the plants from cuttings, layers, or seedlings there is no risk. Is there any sound reason for grafting a plant so easy to raise from layers as the Clematis? There is none, either as to tenderness or difficulty of increase.

Grafting on *Clematis Viticella*.

M. F. Morel, who condemns the use of our common wild kind, uses as a stock *C. Viticella*, which I think is not the best way: the union arising is too fragile. I have had many plants from M. Morel, and hope to have many more, but I have lost some grafted plants, whereas I never lost one of the layered plants.

In dense planting among shrubs any malady is seen but rarely. Many of my plants have borne hundreds of flowers for years, and are, even now, in perfect health. As to Mr. Jackman's repeated statement that the scion absorbs the stock or gets rid of it, anyone who buys a batch from a nursery and takes the trouble to examine the roots will find the two sets of roots in action.

Every season I buy batches of plants and the first thing I do is to take them to a tank and wash out the roots: the "wag" of the native stock is always there.

Soil

It was thought that calcareous soil was cure-all, no doubt arising from the fact that our native species abounds on the chalk hills, but for the Japanese Clematis chalk is not needed. The plants may grow in calcareous soil, but so they do in sandy loam. If anything is helpful in planting a Clematis it is plenty of sharp sand. We never give either mulch or special fertiliser; none is needed.

The Clematis in the Flower Garden.

Having proved beyond a doubt the vigour and beauty of naturally grown plants, my next step was to bring them into the flower garden their right place, though from gardens they are generally excluded. So they were planted on tripods, pergola, wall, and Oak fence as a background to the mixed border, and on almost every surface at hand. And all these places they adorn from early summer to mid autumn.

Increase

In only one nursery, at Richmond, in Surrey, have I recently found some Clematis not grafted, and was glad to find the plants without a vestige of the ugly black wig of the roots of the wild kind. The best way in the nursery of the future is to layer the plant in the stock ground, pegging down the shoots in little pots set around the mother plant. I am writing to my friend Morel, who has raised a number of distinct and lovely forms, to beg him to increase his plants in this way, which gets rid of the fog of guessings about the supposed disease of plants that only ask to be allowed to grow on their own roots.

Miss Willmott tells me she raises Clematis easily from cuttings. From seed of the nobler kinds it is well to raise varieties of merit, though the seed is slow to germinate. The wild species come freely from seed. I sowed the Virgin's Bower (*C. Viticella*) out of hand when forming a new live fence around an orchard, and there it has been ever since, throwing a lace-work of delicate form and flowers over the fence.

There is no more need to graft a Clematis than to graft a Raspberry. It is a short-sighted practice which has driven the loveliest of all hardy climbers from the gardens of Europe. On the contrary, both as to root and branch they are among the most vigorous of hardy climbers. In the loss of Rhododendrons by thousands on the pontieum type on which they were grafted the planter has the satisfaction of seeing the bloom of his favourite for a few years before it gives up the ghost. In the Clematis, even the poor satisfaction is denied him, and in large gardens, with every advantage of soil and climate, they are often unseen. *W. Robinson, Gravetye, Sussex.*

ORCHID NOTES AND GLEANINGS.

NEW HYBRID ODONTOGLOSSUMS.

THREE handsome and distinct hybrid Odontoglossums are sent for recording by Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells, who regard them as the best of their many Odontoglossum novelties up to the present.

The flowers of all three are large, of perfect form and fine substance

ODONTOGLOSSUM VIOLET QUEEN.—This variety was raised between O. illustrissimum (Lambeauianum × ardentissimum) × Armstrongiae, and is the most successful attempt to obtain a perfect flower, mainly of a violet tint, with the colour extending to the lip. The broad sepals and petals are clear violet colour with a slight rose shade, a few slight white markings on the tips, and a narrow, clear white margin. The broadly ovate lip is reddish violet, with small spots in the white marginal band. The column is violet colour and the crest of the lip bright yellow.

ODONTOGLOSSUM PERFECTION.—This fine cross between O. crispum Leonard Perfect and O. Amandum (Pescatorei × Wilckeanum) does ample credit to its lineage. The perfectly-shaped flower has a clear white ground, the sepals having two, and the petals one large irregular blotch of light claret-red occupying two thirds of their surface, with a few smaller spots on the white margin of the segments. The labellum has a reddish-claret blotch in front of the yellow crest.

ODONTOGLOSSUM SERBIA. — This handsome hybrid between O. Ossulstonii and O. Aglaon is of fine proportions, the ground white, the inner two-thirds of the sepals and petals having large, confluent, purplish-red blotches, the bases of the petals being white. The reverse of the flower is coloured purple, the colour showing through to the surface at the tips. The colouring of the lip matches the petals, and the whole flower is well balanced.

NOTES ON IRISES.

AN AUTUMN FLOWERING IRIS

THE sketch reproduced in fig. 63 is of an Iris which does not get much attention or praise when it flowers in June, for then it is overshadowed by finer forms of the spuria section. When, however, it sends up its second show of spikes in mid-September, and when each spike has as many as three or four flowers open at once, it is a much more valuable plant

Its real name is exceedingly hard, or indeed impossible, to discover, for it is one of a numerous company of Asiatic relatives of I. spuria, which seem to abound in every brackish marsh from Smyrna to Srinagar. The oldest name appears to be Pallas' halophila, "salt-loving," and others are Gueldenstaedtiana, sogdiana, and desertorum. It is difficult, if not impossible, to distinguish herbarium specimens of the various local forms, and further confusion has been caused by the fact that all seed exceedingly freely. The seeds germinate readily, the plants grow vigorously, and easily oust any more delicate species near which they happen to have sprung up. Anyone who attempts to obtain a collection of Iris species by raising plants from the seeds offered by botanic gardens and Continental seedsmen will find that a large proportion of the most attractive names have been attached to seeds of some form of this Iris.

The individual flowers are not large, for the blade of the fall is only about three-quarters of an inch in width, the whole flower measuring about 3 inches across. The colours vary, but usually consist of more or less faint purple veins on a pale mauve or cream ground, with a central yellow mark on the blade of the falls. One curious form, which was sent to me as sogdiana by Mme. Fedtschenko, has flowers of a peculiar shade of mauve-purple, which could only be matched among the pallidas, if, indeed, the exact tone ever comes even then.

The seeds of this Iris are curious, and well adapted to the marshy habitat in which it grows in the wild state, for each is enveloped in a

FIG. 63.—IRIS SPURIA VAR. HALOPHILA: ONE-THIRD NATURAL SIZE

loose, but airtight, parchment-like covering, which enables it to float in water. On the surface it is either carried along by any current or blown by the wind until it strands on some bank, where it has more chance of germinating and growing into a plant than if it lacked this covering and sank to the bottom of the water, where the young plant would probably be drowned, even if the seed succeeded in germinating at all.

IRIS ROSENBACHIANA.

THERE seems to be no doubt that, as was suggested in an article in these columns some months ago, two distinct species are really concealed under the name of Iris Rosenbachiana. It was suggested that the two species could be separated by certain characteristics, visible in the dry bulbs, and the sketch reproduced in fig. 64 is an attempt to show bulbs of the two species. That on the right is slightly larger; the fleshy roots taper gradually and their colour is a light brown. On the contrary, the bulb on the left has roots which taper more abruptly, and they are always whiter in colour. It seems probable that the bulb on the right is that of the true I. Rosenbachiana. It flowers a fortnight to a month earlier than the other species when the bulbs are grown together under the same conditions. So far as my experience goes, the flowers of this early-flowering species are always white, with crimson or reddish-purple markings and a conspicuous golden crest, whereas those of the other species are very various in colour, usually of some shade of blue- or red-purple, but occasionally even of a pale yellow with faint purple veins. There is one difference in the flowers which seems to be constant, and that is, that the pollen of the early-flowering form is always yellow, while that of the other is always white.

In her account of the Irises of Turkestan in the *Journal Russe de Botanique*, 1909, No. 5, p. 77, Mme. Fedtschenko says of I. Rosenbachiana: "Flowers large, of various and beautiful colour," and of I. baldshuanica: "Flowers smaller, yellow." This is barely a satisfactory diagnosis of the two species, and it is probable that some of the plants which she took to be Rosenbachiana should really be class[ed] as specimens of baldshuanica. It is not yet certain whether these two plants breed true when raised from seed, and it is therefore impossible to say at present whether we must consider them as two good and distinct species or merely as local forms of the same species. In the meanwhile it may be useful, at any rate for gardening purposes, to say that I. baldshuanica differs from I. Rosenbachiana in being slightly smaller and flowering later, in having white and not yellow pollen, and in having fleshy roots to the bulbs, which taper abruptly and not gradually.

Both these Irises are easy to raise from seed, which should be sown in the late summer or early autumn. By the end of the first year the small bulbs will have no persistent rootlets, but resemble that illustrated at (a) in the sketch. If the soil in the seed-pots is made sufficiently rich, the small bulbs may be left in them until the end of their second year, when they will be found to have developed a root almost as large as, and in some cases even larger than, themselves. Such an example is illustrated at (b) in the sketch. At the end of the second year the small bulbs should be planted out in a sheltered sunny corner, or preferably in a cold frame, and by the end of the third year will have assumed the appearance of that marked (c) in the sketch. A year, or at most two years, later the bulbs will begin to flower and, although in most cases propagation by offsets from bulbs is slow, it will be found that some individuals seem to increase fairly rapidly by this means. A strong bulb is capable of throwing up three or even four flowers in succession, so that the display lasts for a considerable time. *W. R. Dykes, Charterhouse, Godalming.*

Allington Pippin Apples at £280 per Ton.—From Mr G. W. LEAK we learn that Messrs. R. H. BATH, LTD., Wisbech, recently sold a ton of Allington Pippin Apples for £280. These were fine specimens, purchased by a buyer for a North of England co-operative society, who offered the price quoted, i.e., 2s. 6d. per lb. for one ton.

ON INCREASED FOOD PRODUCTION.

POTATO YIELDS

The heaviest yield of Potatos from 1 lb. of seed in a competition at Sutton St. Barnabas, Surrey, was 518 lbs. Every precaution was taken to guard against error and to ensure equal opportunities to the competitors. The sets, which were from Ireland, were graded so that each competitor received 15 tubers. A member of the committee was present at the planting and lifting. When dug each crop was placed in a bag and sealed. The name of the variety was not known to the competitors. Last year the first prize crop in a similar competition weighed 360 lbs. *J. C. B.*

The Barrhead and District plotholders held a competition for the heaviest yield from 1 lb. of seed Potatos limited to 12 sets. The variety was Majestic. Two competitors, working side by side, lifted 35 lbs. and 36 lbs. respectively. Each had one plant that failed, so that there were 22 roots between them. When washed and dried the total weight of these 22 roots was 160½ lbs. The heaviest Potato weighed 2 lbs., the 12 heaviest 18 lbs. 13 oz. There were 304 lbs. weighing 1 lb. or over, 63½ lbs. from ½ lb. to 1 lb., and only 16 lbs. of Potatos weighing less than ½ lb. Of these, 12 lbs. were small. *J. C. Roberts, Hon. President, Barrhead and District Plotholders' Association.*

I was present on September 18 at the lifting of the trial Potatos grown by Mr. E. H. Bartram, Parc Newydd, Abercynon, Glamorgan, for the Board of Agriculture. The results were as follow:

	Roots	Total crop lifted
Edzell Blue	30	160 lbs.
The Ally	15	155½ lbs.
Great Scott	30	227 lbs.
Mr. Bresee	15	118 lbs.
Lochar	30	191 lbs.
Templar	30	147½ lbs.
Tinwald Perfection	30	162½ lbs.
Dominion	30	123½ lbs.
Kerr's Pink	15	123½ lbs.
Majestic	30	216½ lbs.
Golden Wonder	30	159½ lbs.

The seed tubers were planted on April 19, 1918, and lifted on September 18. Three and a half pounds were planted to provide 30 roots. One root of The Ally variety yielded 100 tubers in all, with a total weight of 18lbs. *John Parker, Glamorgan County Horticultural Demonstrator, Pontypridd.*

From one root of Satisfaction I obtained three Potatos weighing respectively 2 lbs. 11 oz., 1 lb. 15 oz., and 1 lb. 1 oz. *J. M. Bloor, Derby.*

THE POTATO CROP

In most districts the earlier varieties of Potatos were very satisfactory, and the tubers were but little affected with disease; but on some soils, owing to a long period of dry weather, the crop was not so heavy as was at one time expected. It is interesting to notice the appearance of Potatos cultivated for the first time on newly turned up pasture in contrast with those grown for the second time on similar ground. Seldom as one is able to judge, where the land was properly prepared, and Scotch or Irish seed planted, there is very little to choose between the crops, and heavy yields should be looked for.

There are still many Potatos in the ground, as the weather has not been favourable for lifting them. It will be wise to lift and store the tubers whilst they are still in good condition. When dug breadths are small, hand-digging will take too long, and the tubers should either be ploughed out or lifted with a Potato digger, of which there are several types on the market. Plenty of hands should be employed for following the machine for the purpose of picking up the crop, but care should be taken not to include any that are blighted, and the "chats" should be picked up separately for pig feeding purposes, as, owing to the prevailing scarcity of animal food, these are sure to be in great demand, and will realise good prices.

There is no better method of keeping "ware" Potatos than by pitting or clamping them, providing it is properly done. Select a high, dry piece of ground and elevate the base above the level of the surroundings. Use a little dry straw for placing the tubers on, build the clamp ridge shaped, in a workmanlike manner, and sprinkle a little slaked lime between the layers of tubers. Lime has a sweetening influence, prevents any diseased tubers contaminating the rest, and generally improves the quality. Put a good layer of straw on either side of the ridge, after which a little soil should be placed thereon; at frequent intervals bring through some tufts of straw for ventilating purposes on either side of the ridge but not along the centre, as is so frequently done. Later, more soil should be placed on the clamp sufficient to ward off severe frosts, and at all times it may sometimes be necessary, even when it is desirable, to place one sort of covering over the whole during long periods of frosty weather.

Resistant Sovereign has proved to be one of the very best, and a good late and fair cropper. It is a great cropper, perfect in shape, quite free from disease, and, above all, the quality is of the best. It much resembles the old Snowdrop in appearance, but, as is well known, that variety was very prone to become attacked by late blight.

Other good varieties that have done well in this district are Midlothian Early, Sharpe's Express, King Edward, Scottish Farmer, Iron Duke, Great Scott, President, Arran Chief, and British Queen.

The illustration in fig. 65 shows part of 30 rows of Potatos in the park at Aldenham House, Elstree, this being the second season the park has been cropped with Potatos. *Edwin Beckett.*

IMPORTANCE OF PHOSPHATES FOR POTATOS

I have long been of opinion that the low-lying portions of the land in the neighbourhood of Bath are deficient in available phosphates, and further experience has confirmed my belief. On these lands it does not appear to be so, for good fruit is produced on comparatively slender growth where the trees are well cared for, and Potatos also are of good quality without over-luxuriant haulms.

A low lying plot taken in hand in March, 1917, was in rather poor condition, and suspected of being short of humus, phosphates and lime. As a nitrogenous manure was necessary, it was not advisable to apply caustic lime at the same time, therefore gypsum was applied and as no superphosphate was to be had, it being too late to

Fig. 64. Bulbs of Iris fosteriana, eight to the left, at first year; in second year; third year seedlings (see p. 164).

Fig. 65. Potatos grown as in the park at Aldenham House, Elstree.

apply basic slag, steamed bone-flour was used, and as much wood-ash and burned vegetable matter as could be had. The Potatos were planted in trenches, and stable manure which was already partly decomposed was mixed with the soil between the trenches, so that it could be used for earthing-up without much of it coming in direct contact with the young growths, and none of it would touch the seed tubers. A fair crop was produced, but the quality was indifferent, and the haulms were much too vigorous, many of them being 6 feet in length.

In the spring of this year Potatos were not planted on the same ground, but on that which had been manured for other crops the year before, and to which another application of lime was given in the autumn. No manure whatever had been applied to this plot since the spring of the previous year, and none was given at the time the Potatos were planted, with the exception of a little soot to ward off insect pests, and wood ash. No phosphatic manure was wanted, because steamed bone flour was applied the previous year.

The seed tubers, which were not in the best condition, were planted in trenches 3 to 3½ feet apart, and 15 to 18 inches asunder in the rows. The early part of the season was very dry, and Potatos, as well as other vegetables, suffered from drought, but these, being planted in trenches and earthed up deeply, suffered very little. They yielded a good, clean crop: the variety Gordon Castle gave an average of 6 lbs. to the root: one root produced 8 lbs. 5 oz., and many 7 lbs. and over. The quality also was good. This was very satisfactory, but as steamed bone-flour is now out of the question, having trebled in price within a few years, basic slag will be applied this autumn. The seed tubers will be selected and carefully tended. They will not be planted on the same ground, but on that which was manured for another crop last spring. An acre of Potatos planted 15 inches apart in the row, with 3 feet between the rows, would require 11,520 sets, and these, yielding 6 lbs. each, would give a total crop of 30 tons 17 cwt. 16 lbs.

On land adjoining the forementioned, which was not treated to phosphatic manure, but had a good dressing of wood ash, and was planted with the same varieties, from the same source, the crop was not a heavy one, and many of the tubers were small.

Besides the lesson in phosphatic manuring, the foregoing experiment shows the folly of planting too closely.

When basic slag cannot be applied in the autumn or early winter, superphosphate should be used at planting-time, and, if the soil is not deficient in lime, another dressing may be given at the final earthing-up.

I know a spot not far away where Potatos have been grown successfully on the same ground without change of seed for half a century. *Wm. Taylor.*

FOOD PRODUCTION AT LETCHWORTH.

Several thousand Belgians are employed in the large munition works at Letchworth Garden City, most of them being invalided soldiers and members of the professional classes who, being unable to follow their ordinary vocations, took up this important national work.

When the need for increased food production became evident, a big allotment scheme was started in the district, and a lecturer was appointed by the Belgian Board of Agriculture.

The results of the combined efforts of growers and instructor, aided by the directors of Messrs. Kryn and Lahy Metal Works and the Belgian Board of Agriculture, have been encouraging. A garden produce competition was held on September 29 by the four hundred members of the Belgian Gardening Club, this being the second year in which a show has been held by the club. The exhibition revealed the important contribution made to the food supply by these munition workers, in spite of their working long hours on heavy tasks. *E. B.*

The Week's Work.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Vanda. — Towards the end of the present month Vandas of the tricolor and sanvis section will commence to root freely, and any necessary repotting is best done at this period. Specimens that are well furnished with leaves and with roots in good condition should not be subjected to much root disturbance unless a larger receptacle is needed, but some of the old materials may be removed from the surface and replaced with fresh. Plants that have become leggy through losing a quantity of their bottom leaves, and are provided with plenty of live roots up the stem, should be removed from the pots and as much of lower part cut away as will bring the lowest pair of leaves, when the plant is again placed in the pot, almost down to the rim. After severing the stem place the plant in the centre of the receptacle, with a few flat crocks over the bottom. Cover the crocks with a layer of clean Sphagnum-moss, over which spread the roots, and carefully work in amongst them some clean crocks and Sphagnum-moss, then distribute more roots in a similar way until the rim is reached, finishing with a surface of clean, picked Sphagnum-moss. In turning the plants out of the receptacles it will be found that some of the roots will cling to the sides, and care must be taken not to damage them. Each growth should be tied to neat stakes to keep the plants firm and upright. The bottom aerial roots should be pegged to the moss, while those higher up the stem should be directed downwards to the compost. Shade the plants from sunshine, and keep their immediate surroundings moist by syringing frequently around and between them. The plants will not require water for a few days after they are potted, but later, as often as the surface moss becomes dry, it should be sprinkled with water in order to keep it green and healthy. These Vandas grow well in the intermediate house or the cooler end of the Cattleya house. They are subject to the attacks of a small brown scale insect, that attaches itself firmly to the leaves; great care is necessary in destroying the pest or the leaves may be permanently injured. Vanda Kimballiana and V. Watsoni are developing their flower-spikes, and the atmosphere should be kept rather drier and warmer than hitherto, but give sufficient water to keep the Sphagnum-moss growing. Less moisture will be needed after the flowers are expanded.

Oncidium.—Such Oncidiums as O. varicosum, O. Forbesii, and O. crispum, are now developing their flower-spikes and must not be allowed to suffer from drought at their roots, or the flower-buds may turn yellow and drop. These species produce strong, branching inflorescences, therefore only robust, well-rooted specimens should be allowed to flower. Weakly plants should have the flower spikes removed as soon as they appear, and be given every encouragement to grow vigorously. In no case should the flower spikes be allowed to remain on the plants after the pseudo-bulbs begin to show the least signs of shrivelling. O. concolor will have finished its season's growth, and requires less water at the roots, but it must not be allowed to become quite dry at any time. O. Papilio and O. P. Krameri anum, which produce a succession of flowers from their slender stems, should not be allowed to become dry at the roots, and the flower stems should be removed after three or four flowers have developed. These interesting plants grow well in shallow Teak wood baskets suspended in a light position in the warmest part of the Cattleya house.

Cymbidium.—Plants of Cymbidium insigne, C. Lowianum, C. Tracyanum, and the many hybrids that are now sending up flower spikes should be well supplied with water at the roots, whilst others that are more backward in this respect should be kept rather dry, otherwise new growth will commence and the plants fail to bloom. C. grandiflorum has finished its growth, and flower-spikes will soon be appearing from the pseudo-bulbs made the previous year. To ensure success in flowering this species, the plants should be grown in a cool, light position, and their roots kept somewhat dry during the winter. C. eburneum should be grown in a less exposed part of the house, and, as plants of this species have only small pseudo-bulbs, they should not be allowed to become quite dry at the roots.

Disa.—The present is a suitable time to commence the repotting of Disas, but repotting is only necessary about every second year. The first to need attention will be D. Luna and some other hybrids, whilst the brilliant D. grandiflora may receive attention at a little later period. Ordinary flower-pots or rather deep pans form the best receptacles, and for well-rooted specimens these should be at least two sizes larger than those the plants now occupy, so that very little root disturbance will be necessary. Good drainage is essential. The rooting material may consist of good fibrous loam, Sphagnum-moss, and a little peat, with a fair sprinkling of crushed crocks and coarse silver sand. The compost should be pressed moderately firm, and the receptacle filled to just below the rim. With the last layer of soil a few living heads of Sphagnum-moss should be incorporated, to help keep the roots in a moist condition. Disas should not be allowed to suffer from drought at any time, as they have no decided season of rest. Place them in the coolest and shadiest part of the Odontoglossum house, near a ventilator, where they may receive fresh air at all seasons. When vaporising the house, remove Disas to another structure until the fumes have escaped, or the leaves will become disfigured. Specimens that are pot-bound may be divided and made up afresh: arrange together portions of uniform size, the object being to have all the plants in the one pan in flower at the same time. One watering should be given to settle the compost, and for some time to come spraying once or twice each day will be sufficient to keep them moist. The plants should be sprayed overhead occasionally with a liquid insecticide, in order to ward off attacks of thrips.

THE HARDY FRUIT GARDEN.

By Jas. Hudson, Head Gardener at Gunnersbury House, Acton, W.

Late Peaches and Nectarines.—The fruits of late Peaches and Nectarines, with but few exceptions, will now have been gathered. Any attention needed should be given the trees, and if the borders are in need of renewal, let the work be done as soon as possible. Follow the directions given for the earlier varieties, and thin out the wood rather more than for the latter. If a good top-dressing of fresh soil is all that is considered needful, let that be applied before inclement weather arrives. Where shortage of labour precludes even this procedure, apply a very moderate top-dressing of an artificial compound, in which phosphates combined with potash predominate. Such a compound can be easily chosen if the percentages issued by the makers are considered. Lightly fork the manure into the surface soil; it will soon be carried lower down by the rains. If possible, do not crop these borders after they have been in any way treated, but rather let them be left vacant during the coming winter.

Planting Young Trees.—Planting should be done immediately the trees arrive from the nursery. Do not lay them in with the view of postponing the work for a few more weeks, as this is a dangerous practice, but if they arrive at the end of the week, this must be done. Before planting, examine the roots, and remove any sappy ones that point in a downward direction. Place a few roofing slates under the roots to further prevent this tendency. Plant in good, fresh soil, without the addition of animal manure. Remove injured roots, and thin out very sappy growths, but do not otherwise prune, but rather leave this work to be done in spring.

Root-Pruning and Planting Apricot Trees.—In many instances it may be found expedient to root-prune Apricot trees if they are growing too freely. I know a case where a good practical gardener had greater success when he partially lifted his trees every second autumn. These were

trees with plenty of vigour. If root pruning were generally adopted, it might I think be the means of preserving the trees. Use a liberal amount of old mortar rubble when filling in the soil and do not employ animal manures. When planting young trees provide good drainage by means of old brick rubble, with the mortar still adhering. Let this be a foot thick at the least, and ram the soil firmly as the work proceeds. The border should be somewhat higher than the level of the surrounding soil, so that it does not receive an undue amount of rainfall. It should be borne in mind that Apricots in their native habitat have to go through a long period of drought and endure extremes of heat and cold. I feel convinced that if we protected the soil in which Apricot trees are grown in such a way as to throw off the winter rains it would be all the better for the trees. Apricots in this country flower too early for their well being.

FRUITS UNDER GLASS

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire

Fruit Trees in Pots.—The shoots of trees now in the open which were repotted or top-dressed as advised in the CHRONICLE of August 10, should now be thoroughly ripened. Preparations must be made to protect the pots from frost. If they are standing on a dry base in a sheltered site, they may be protected where they stand. Plunging the pots over their rims in ashes, leaves, litter, or Bracken will carry them safely through severe weather. When so doing the pots care must be taken that the plants do not suffer from lack of moisture at the roots, especially during a long period of rainless weather. When fruit trees in pots cast their buds in the spring the cause can generally be traced to dryness at the roots in winter. Keep the pots well covered and the roots moist and there will be no trouble in this respect. At a later period, when every leaf has fallen, the trees should be carefully washed with strong soapy water.

Successional Trees in Pots. No time should be lost in completing the work of rooting late trees. In many cases, by carefully reducing the ball of soil and roots, it may be placed in a clean, dry pot of the same size as before; this will allow room for nearly three inches of fresh compost to be worked down to the base. All the young fibrous roots should be carefully preserved and the strongest roots shortened. Cover the clean crocks a few inches deep with the more fibrous parts of the compost and make it quite firm with the rammer. Hard ramming is most essential when repotting fruit trees, as this not only encourages the roots to make new fibres, but prevents water from passing away without wetting the whole of the soil. Strong, fibrous loam, old lime rubble, bone meal, burnt garden refuse and soot, with a small portion of decomposed manure if the loam is poor, will form an excellent compost for fruit trees of all kinds.

Top-Dressing Trees in Pots. For trees that only need top-dressing it will suffice to correct the drainage, remove the old surface soil to a depth of 3 or 4 inches, and replace with a slightly richer compost. Give all newly potted and top-dressed trees one good watering, and, if possible, place them in a cold house for a few weeks before finally plunging them outside, otherwise, during a long spell of wet weather they will remain in a saturated condition, which greatly retards root development.

Young Trees. It may be necessary to introduce a few maiden Apple, Pear, Plum, Cherry, Peach and Nectarine trees to grow on ready to replace those showing signs of exhaustion. All these readily respond to cool house treatment, and now is a suitable time to obtain the trees from a nursery, if there is no reserve stock. Directly they arrive, prune the trees into shape and after shortening back all strong or injured roots they should be placed in clean, well drained pots varying in size from 9 to 11 inches. The compost should be in a friable condition, and the firmer it is rammed the better. When potting is completed, plunge the pots deeply in leaves or Bracken, in a sheltered position outside.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Asparagus.—As soon as the foliage dies cut the stems off to within a few inches of the ground and carefully clear the beds of all weeds. Where the soil is of a light, sandy nature and well drained, autumn mulching may be safely and probably advantageously practised. The beds should be top-dressed with half-rotted manure, and sufficient soil thrown out of the alleys to lightly cover the manure. On naturally heavy soil of a very retentive character, the common practice of mulching should not be done. It is not frost alone, but an excess of moisture, or perhaps the two evils combined, that causes the loss of many of the crowns. To guard against this trouble as much as possible lightly clear the beds of weeds, and top-dress it with some light material. Much of the rain will then run off the bed, which will be drier and warmer in consequence. The manure may be applied next spring. This treatment applies more especially to beds on the level, but even on raised beds mulching may safely be delayed until the spring.

Celery. Take advantage of dry weather to earth up late Celery as the plants complete their growth, following the directions given in previous numbers.

Forcing Rhubarb. Lift a few strong roots of suitable varieties which have been exposed with well ripened crowns, leaving them fully exposed a few weeks before placing them in 55° to 60° warmth. A Mushroom house or similar structure which can be kept darkened, and with heat and moisture, will ensure supplies of forced Rhubarb by Christmas.

Endive. After this date no more of the roughly blanched Endive is only slightly inferior to it, if any, in point of crispness and flavour. Only those who have to supply salads daily throughout the year can fully appreciate the value of a good supply of Endive. The hotter and more strongly they are grown the more liable are the plants to be spoiled by frosts. Protection should therefore be afforded them either by frames or letting them and placing them in a cool house secure from frosts. Blanching should not be commenced until the leaves are nearly or fully grown, the number of plants being prepared at weekly intervals according to requirements. If blanching is commenced too soon it stops the growth of the plants, moreover, Endive keeps badly after it is blanched. Inverted pots with the drainage holes covered to exclude the light offer a quick and ready way of blanching Endive and also protects the plants. Probably the best Endive is obtained by placing strong plants in a warm Mushroom house in small batches and keeping them well supplied with moisture without direct overhead watering.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire

Plants for Forcing. It is important that plants which are to be forced into flower early should be well matured. Lilacs, Prunus, Pyrenses, Wistarias and Deutzias which have been planted in the open should be dug up and placed in pots of suitable size. Ordinary soil is suitable for these plants. Specimens grown in pots and not needed for early forcing should be plunged up to their rims in ashes as a precaution against frost.

Roses in Pots.—If a suitable house can be found for the cultivation of Roses in pots, a few should be certainly grown, as no flowers are more appreciated than Roses at any time of year. No time should be lost in securing plants for this purpose, for the earlier they are potted the better. A suitable compost may be made by mixing good fibrous loam with cow manure, crushed brick rubble, and a little bone meal or crushed bones. Before potting the plants, cut back the stronger roots, but preserve all the fibrous roots. Roses suitable for pot culture are Madame Abel Chatenay, Mrs. J. Laing, Lady Hillingdon, Liberty, Richmond, and Sunburst. Among the climbing varieties, Dorothy Perkins, Minnehaha, Blush Rambler, Paul's Scarlet Rambler, and Electra will be found suitable for cultivation in pots, and they are most suitable for conservatory or house decoration. When potted, they should be plunged in ashes as a safeguard against frost.

Climbing Roses.—If the final thinning of the young growth has not been done, this work should be no longer delayed. Some varieties, such as Fortune's Yellow, usually develop a great deal of lateral growth. This must be cut back to two or three buds. Give abundance of air on all favourable occasions, but do not permit cold draughts, as these will cause mildew to develop on the foliage. As a precaution against this disease the plants should be dusted occasionally with sulphur. The roots of climbing Roses must not be allowed to suffer for lack of water, and old established plants may still be given some form of stimulant.

Freesia.—If Freesias were potted early, they will now be well rooted, and a few pots may be placed on a shelf near the glass in a warm house. As growth advances the roots may be given an occasional watering with weak soot water. The main batch of Freesias must be kept growing under absolutely cool conditions, using fire heat only to keep out frost. The shoots should be supported to neat stakes before there is danger of them breaking.

Schizanthus. Pot on seedling Schizanthuses in 6 inch pots as they become large enough. The earliest plants should be shifted into larger pots; a compost of fibrous loam, leaf soil, a little manure from a spent Mushroom bed, and sharp sand will be suitable for them. Arrange the plants on a cool base near the roof glass, and keep them growing in cool conditions at all times.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian

Planting Bulbs. Where there is a superfluous number of bulbs which may, with advantage, be thinned, the present is a suitable time to make fresh plantations on grass and elsewhere. Fritillarias are very choice flowers, and the old red Crown Imperial arranged near a background of dark foliaged shrubs is splendidly beautiful. Scillas, too, are charming spring flowers, one of the choicest being S. italica, which does well in grass. The Muscaris are rather inclined to the out, but the common M. botryoides increases so rapidly that there is always enough to spare to make good any failures. It is a great help to established colonies to surface dress the plants with a compost of well rotted manure and rich soil.

Spring-Flowering Plants. The flower beds should be filled with spring flowering plants directly they are cleared of the summer occupants. There is no need to make great preparations, and were it not that forking the soil gets rid of much unsightly material, bulbs, Wallflowers, and similar plants might be planted without any preparation at all, any fertilising material needed being added as a surface dressing in February. Firm soil is drier and less liable to frost eruption than that which is loose, and on that account alone the ground should be well firmed as planting is proceeded with.

Pelargoniums. It will be almost impossible to winter cuttings of Pelargoniums without the use of fire heat, but old plants may be lifted and saved and the stock by this means preserved. The method consists in partially disrooting the plants after lifting, denuding them of foliage and keeping them quite dry until the spring, when they may be started into growth either in boxes or pots. They make remarkably fibrous plants, far more so than autumn struck cuttings do. During the period of rest dryness is essential, no moisture, and, of course, a temperature never near freezing point. Where there are means of keeping rooted cuttings a very low temperature is suitable, provided the soil in the pots or boxes is kept dry.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 47.3°

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, October 23, 10 a.m.: Bar. 30.1; temp. 52°. Weather: Slight fog.

A Chamber of Horticulture.

The need for an organisation in which the whole interests of the horticultural industry and profession are focussed has long been urged by the more enlightened members of the trade, and steps which have recently been taken give promise of the formation of such a central body, which will be known as the Chamber of Horticulture. Prosperous pre-war conditions did not seem to call so urgently for this focussing of interests, but the war has brought many troubles to horticulturists as to members of other trades, and with the passing of the Defence of the Realm Act, the Corn Production Bill, and other controlling measures the need for a central horticultural body has become increasingly pressing. The horticultural trade has discovered its inability to offer effective objection to or provide strong defence against impending controlling measures likely to press hardly upon it. On the contrary, this lack of focussed co-operation made the work of the Horticultural Division of the Food Production Department extremely difficult, as those in charge found no central body to whom they could appeal for statistical information to help them in the difficult circumstances that arose continually; consequently horticulture failed to secure for itself the recognition its great and far-reaching activities deserved. Happily, this reproach promises to be removed in the near future by the establishment of a Chamber of Horticulture. This endeavour, due chiefly to the initiative of Mr. H. Morgan Veitch and Mr. George Monro, jun., will have the warmest support of all who desire the advancement of horticulture. Already the scheme has promise of powerful support from prominent men in the trade, including market growers, fruit growers, flower growers, and seed merchants. A short while ago members of the horticultural trade were invited to meet at Donington House, Norfolk Street, Strand, London, for the purpose of considering the advisability of forming a Chamber of Horticulture. They decided in favour of its establishment, and appointed a sub-committee to draft Rules and Articles of Association, select and recommend a whole-time secretary, and endeavour to find suitable offices in or near Covent Garden. The preliminary work occupied a large amount of time at many meetings, but on Friday, the 18th inst., the work had proceeded sufficiently to enable the sub-committee to place its recommendations before the larger body by whom it was appointed. Unfortunately, the Rules and Articles of Association could not be placed before this meeting, as they were still in counsel's hands. In due course they will be published in the horticultural Press, so that they may be thoroughly considered and criticised before they are submitted to a mass meeting of traders to be duly advertised and held in London. Both Mr. Monro, jun., and Mr. Morgan Veitch outlined the aims and objects of the Chamber, and insisted that the work now carried on by horticultural trade societies, associations, and federations would be as necessary as ever, and the Chamber will not interfere with their activities in any way, but encourage and help them. The Chamber will be the direct means of communication between Parliament, Government Departments, and railway companies, and the horticultural trade as a whole. It will be representative in the highest degree by means of delegates from associated trade societies and private members, by whom the executive council of thirty-six members and the trade committees will be elected. Dr. Keeble, of the Food Production Department, and Mr. A. G. Rogers, of the Board of Agriculture, were present at the recent meeting, and the latter considered the compilation of statistics relating to horticulture should be almost the first business of the Chamber. Dr. Keeble said it was high time the public understood the difference between horticulture and agriculture, and a Chamber of Horticulture would be the means of making the distinction widely known by showing the national importance of the horticultural industry. At present, he said, there were no statistics to indicate that importance, consequently the difficulties in the way of making Government Departments understand the extent of this industry and the money invested in it were very great. He believed proper statistical information from various branches of the trade, collected by the Chamber, would prove beyond all question the immensity and national importance of horticultural activities. His own work in relation to Food Production would have been greatly simplified had such information been ready to hand. Both Dr. Keeble and Mr. Rogers made a strong point of the fact that Government Departments were not antagonistic; those in charge needed all the assistance the trade could afford, and desired to give as much information and help as possible. Dr. Keeble heartily supported the formation of the Chamber of Horticulture, suggested the appointment of corresponding members, and urged the Chamber to undertake experimental inquiries, particularly in connection with mechanical cultivation, and incidentally remarked that the Council of Industrial Research might be expected to contribute towards the conduct of experimental work carried out on the right lines. Mr. Agar, Renter Warden of the Gardeners' Company, expressed hearty approval of the new movement. Alderman Moore, the Master of the Fruiterers' Company, was appointed hon. treasurer of the Chamber, and Mr. R. Wynne secretary, appointments which Mr. A. J. Monro (with a happy play upon the words "win" and "more") considered a happy augury for the future. With the establishment of a Chamber of Horticulture it is proposed to acquire a building wherein all horticultural trade organisations, including the parent body, will find suitable office accommodation. The financial prospects of the Chamber are excellent, provided the trade associations attach themselves and contribute their quota, and that more private members are forthcoming. Already, thanks to Messrs. Geo. Monro, jun., J. T. Poupart, J. Rochford, Alfred Watkins, W. G. Lobjoit, G. Shawyer, H. O. Larsen, W. Seabrook, R. Robbins, and F. Ladds, an income of nearly £1,000 a year for five years has been assured.

"Daily Mirror" Potato Competition.—Following a series of local competitions held throughout the country the final competition for the prizes offered by the *Daily Mirror* for the best dishes of five Potatos was held at the Memorial Hall, Farringdon Street, London, on Wednesday, the 16th inst. More than one thousand dishes of excellent Potatos were exhibited, and the premier award of £500 was won by Mr. F. J. BREACH, Eastbourne, with five wonderfully fine specimens of Up-to-Date. The other leading prizewinners were Messrs. F. F. BUTCHER, Ashford, Kent (£100); JOSEPH DAY, Berkhamsted (£50); R. W. BASTOCK, Warwick (£25); G. H. GORDON, Lincoln (£10), and, in addition, thirteen competitors secured prizes of £5 each. The exhibition was opened by Mr. CLYNES, of the Ministry of Food, and Dr. KEEBLE and Major BELCHER were also present at the opening ceremony. The generally expressed opinion was that the competition had been the means of encouraging and extending the cultivation of Potatos and thereby increasing the supply of a most important article of food.

Hops.—The preliminary statement of the Board of Agriculture on the produce of Hops shows that the amount of Hops produced in 1918 is 130,272 cwts., compared with 220,719 cwts. in 1917, whilst the acreage is 15,666 and 16,946 respectively. The total production of Hops this year is about two-fifths of the average production of the past ten years, on an area which has been reduced to less than half the pre-war average. The yield per acre (8.32 cwts.), while 4⅞ cwts. less than last year, is, however, only 1⅞ cwt. short of the average.

The Canadian Fruit Crops.—According to the *Board of Trade Journal* the official fruit crop report for September places the Nova Scotia Apple yield at 400,000 barrels, or slightly more than half of last year's production. The embargo on Apple exports to Great Britain, the report states, is discouraging to Nova Scotia growers, but the orchards are being kept in good condition. Conditions in Quebec Province are described as "lamentable," because of the destruction last winter of old Fameuse orchards. The hope is expressed that the farmers will replant these orchards. In Eastern Ontario there

is a medium crop of certain varieties of Apples. There is also a fair crop in Central Ontario, but the quality is below the average. In Western Ontario, autumn varieties are one half a crop, and winter varieties 35 per cent. There is a fairly good crop in the Georgian Bay district. Earlier reports on the Niagara peninsula Peach crop are confirmed by the September report. The total yield will be slightly less than in 1917, and probably not more than 40 to 50 per cent. of an average crop. The Apple crop in the inland valleys of British Columbia will average about 10 per cent. less than in 1917, but is of better quality and size. Pears are a very large crop, at least 50 per cent. larger than last year, while Plums and Prunes also show a big increase.

Richardias.—The four best species of Richardia are R. africana (syn. æthiopica), R. Elliottiana, R. Pentlandii, and R. Rehmannii, all of which are illustrated in fig. 66. The first-named is by far the most popular in this country, being largely grown by market gardeners and in gardens generally as a decorative plant for the conservatory. R. Elliottiana and R. Pentlandii, the yellow Arums, are more tropical in their requirements and more Caladium-like in their behaviour under cultivation. They are therefore less easy to manage, yet there are few more beautiful Aroids than a well-grown example of either. They are often wrongly named in gardens, though they are readily distinguished, R. Elliottiana having spotted leaves and wholly yellow spathes, whilst in R. Pentlandii the leaves are not spotted and the spathes are dark purple at the base. They differ from R. africana in being deciduous, their resting period being marked by the death of everything except the tuber, whereas R. africana has a short, perennial stem, or rootstock, which is very prolific of offsets, and, although it loses many leaves annually, it is not deciduous. R. Rehmannii differs from all the other known species in having lanceolate leaves, which are green with a few linear blotches of white. The spathe is usually white, greenish-yellow at the base, but it is sometimes found with rose-tinted or even wholly vinous-red spathes. Whether this is a varietal difference or due to some special external influence has not yet been determined. Tubers have been known to produce coloured spathes at one time and white at another. Hybrids between these several species have been recorded, though it is doubtful if they are more than garden sports. There are several well-marked varieties of garden origin of R. africana. Other species of Richardia in cultivation are hastata, melanoleuca, and albomaculata, but they are not of much account as decorative plants. According to Mr. N. E. Brown, in *Flora of Tropical Africa*, R. Pentlandii is a synonym of R. angustiloba, first described by Schott in *The Journal of Botany* in 1865. It was introduced into cultivation in 1902 by Mr. R. Whyte, Pentland House, Lee, who showed it in flower in that year at a meeting of the R.H.S. when it was awarded a First-class Certificate. R. Elliottiana was shown two years before by Captain Elliott, Farnborough House, Hampshire, and was also awarded a First-class Certificate.

FIG. 66.—RICHARDIAS.

R. ELLIOTTIANA. R. AFRICANA (ÆTHIOPICA). R. RHEHMANNII. R. PENTLANDII.

Exhibition of Allotment Produce.—An exhibition of produce by the successful competitors in the Cereal and Root Allotment Holders' Competition, arranged by the Sulphate of Ammonia Association, will be held on Thursday, the 31st inst., at 36, Horseferry Road, Westminster, London. The exhibition will be open from 12 a.m. to 4 p.m.

Moss as a Dressing for Wounds.—The value of Sphagnum moss as a surgical dressing is now generally known, and there are 45 depôts in Ireland to which the moss is sent to be made up into surgical dressings of standard sizes. Over one hundred collecting stations scattered over the country supply moss to the Royal College of Science in Dublin. Nearly a million finished articles have now been exported, apart from the work done by the Ulster Sphagnum Moss Association. In 1915 the demand on the Irish organisation came almost entirely from France, but gradually and steadily it increased, till now a constant stream of supplies goes to military hospitals in Ireland, England, France, Italy, Serbia, Egypt and Mesopotamia.

War Items.—Messrs. Laing and Mather, nurserymen, gave to the Border Union Agricultural Society, without any reservation, the entire nursery stock in their Kelso nursery for sale on behalf of the Edinburgh Hostel for Limbless Soldiers, Newton Don Red Cross Hospital, and the R.O.S.B. Prisoners of War Fund. Four auctioneering firms gave their services free at the sale, which was held on the 12th inst. There was a very large attendance, and the sum of upwards of £2,000 was realised by the sale.

The many friends of Mr. A. H. Cooper, gardener at Broadway Estate Gardens, Laugharne, Carmarthenshire, will learn with regret of the death of his son, Mr. A. W. Cooper, who was killed during the evening of the 3rd inst. whilst his platoon was advancing across the open to capture a hostile trench. In a letter informing Mrs. Cooper of her son's death, his commanding officer wrote: "He will be greatly missed, for his cheerful manner had endeared him to all of us."

—We regret to learn that Gunner A. W. Berry, R.G.A. (Siege Battery), was killed by a bomb on September 15 last while his battery was moving to a fresh position. Before enlisting, Mr. Berry was for many years employed in the Hampton Court Palace Gardens. His particular work was on the "Long Border" and the rose beds, which were special features of these public gardens in pre-war days. His genial disposition and pleasant manner in answering the manifold questions which always fall to the lot of workers in public gardens made him as popular with the many regular visitors as he was with his fellow-employees.

Official notification has been received that Private Thomas Henry Vaughan, Royal West Kent Regiment, youngest son of Mr. and Mrs. F. Vaughan, of Heathcote, Boughton Heath, Chester, was killed in action on September 19, at the age of 23 years. Private Vaughan, before joining the Army, worked with his father as a market gardener. He was awarded the Military Medal recently.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

The Fuel Problem.—Allow me to cordially support the remarks on the fuel problem so appropriately made in your issue of September 28. I will quote one sentence only of your leader, viz.: "It is surprising how many plants are able to withstand a lower temperature than we have been accustomed to provide for them." And fruits, too, may I add, for I have been much interested during this past season in two vineries under the care of Mr. Geo. Reynolds, in the Queensbury Park Gardens. No artificial heat whatever has been used from start to ripening, yet the Grapes were excellent, the bunches being of medium size, with berries somewhat beyond the average, and the finish all that one could desire. When I say that the varieties were Muscat of Alexandria and Madresfield Court, each in a house by themselves, I think it is a remarkable achievement, and in a season that has not, at times, been all that one could wish from the point of perfecting a crop such as this, and a heavy crop too. These vineries are of average size, three-quarter span in shape with an abundance of air space over the vines and an abundance of lights, with ample means of ventilation. The borders are all inside. In my own case, I have succeeded better than usual this year with Tomatos, and without the use of fire heat. With respect to plants, it will be well, as you advise, to reduce the number of all decorative plants, and keep the fires as low as possible. Many greenhouse plants are safe when the thermometer does not fall below 32° Fahr. *Jas. Hudson, Gunnersbury House Gardens.*

"Rogues" among Potatos (see pp. 83, 102, 122, 142).—The question raised by Mr. Jackson on this subject is worthy of more than passive notice, and the point to which he draws attention deserves careful consideration. Passing over mere variations in colour, I venture to think that mutants do certainly arise among Potatos, but, as Mr. Jackson has pointed out, they are too often considered to be rogues, and nothing more. It is, of course, extremely difficult to distinguish between what is a "rogue" and what is an unequivocal example of mutation. The great majority of Potato growers are dealing with conditions of cultivation under which the elimination of "rogues" is a difficult matter. Unless what Mr. Arthur W. Sutton refers to as "suitably controlled conditions" are thoroughly ensured, one cannot discern between what are genuine mutants and pure and simple "rogues" with any degree of accuracy. For example, one has to be certain that every tuber used for planting is true to type; that the soil upon which planting is done is absolutely free from "ground keepers" (or tubers left in the soil from some previous crop); and that no tubers exist amongst any manure that may be used. When a trial is made under such conditions, and the experimenter is absolutely sure that no error can possibly arise from mixing, then, if what is generally termed a "rogue" should appear in the trial, I hold that the grower is entitled to consider that a mutant has arisen and is worthy of being grown for the purpose of further examination and comparison. I have long held the opinion that the Potato is in a state of mutation—this fact has arrested my attention on many occasions in a long experience of the matter—but owing to a doubt as to the trueness of the stocks used for seed sets or the condition of the soil I have hitherto had to pass what I thought to be mutants owing to the element of uncertainty. I have observed, as one example amongst several, that a certain early Potato has consistently produced amongst its crop an odd tuber or two of something that is almost identical with Epicure. But, as already stated, I have never been completely satisfied that this mutation was accomplished under "suitably controlled conditions." There was always the element of doubt which could never be satisfactorily disposed of, and I therefore preferred to call what resembled Epicure a "rogue." Until the beginning of last year I have never had the opportunity of experimenting upon this aspect of Potato cultivation under conditions that were beyond doubt, but I am now favourably situated in this respect. Mr. Arthur W. Sutton will, no doubt, be interested in the following experience. Last year I was given one tuber of Edzell Blue by one of the officials of the Board of Agriculture for Scotland, with the assurance that it came from the original stock of that variety. It was cut into one or two portions bearing "eyes," and cuttings were also taken. The plants were grown in virgin soil free from manure of any kind—and the crop was kept for seed and planted in spring. One plant the seed set of which was true to type—has produced several kidney shaped tubers totally different in character from Edzell Blue. They are not only distinct in shape but in colour, the texture of the skin, and the vascular system of the tuber. Were not the matter beyond doubt, in my mind, so far as accuracy is concerned, I should have treated these distinct tubers as "rogues" in the ordinary way, especially so as many stocks of this excellent variety are not wholly true. This mutation—for such I hold it to be—will be grown on and carefully watched. Mr. Cuthbertson has had an opportunity of examining these tubers.

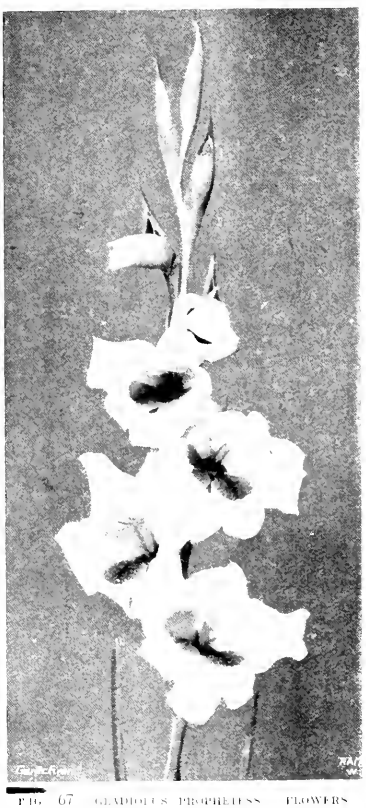

FIG. 67.—GLADIOLUS PROPHETESS.—FLOWERS CREAM WHITE, BLOTCHED WITH REDDISH BROWN.

I have also a white tuber from Edzell Blue (for the second time), but this is what I term a simple and common example of colour variation such as has already been dealt with by Messrs. Cuthbertson and Sutton. I would remind Mr. Sutton that there is nothing to prevent what I call "mutation" among Potatos, and new varieties can undoubtedly be obtained by asexual means. In dealing with almost any commercial variety of Potato one has to remember that its parents are not its only ancestors, and its progeny, of sexual or asexual derivation, is capable of a wide variation in consequence. *George M. Taylor, Mid-Lothian.*

Citrus trifoliata.—May I draw attention to an error which has somehow crept into my note on this plant? Its leaves are described as "trifoliate." Trifoliolate is the word which should have been used, and instead of lateral leaves, it is lateral leaflets that I should have written. In adopting the genus Aegle, altered, however, to Citrus, I followed Mr. Bean in *Trees and Shrubs Hardy in the British Isles* as the latest guide one could follow. I quite agree with Citrus. Indeed, I think it is to be preferred for this plant, but Mr. Bean probably had some definite reason for adopting the genus Aegle. The *Index Kewensis*, as pointed out at various times, is not always to be regarded as an authority on nomenclature—it is a book of reference to authorities. The *Genera Plantarum*, which is a book of responsible determinations, so defines the genus Aegle, that this plant must be included. The single leaflet of Citrus is recognised and the genera Citrus and Aegle are contrasted "1-foliolate" and "3-foliolate." Mr. Bean no doubt followed *Genera Plantarum*, and so does the *Kew Handlist of Trees and Shrubs*. While this plant strikes one as being a Citrus, Aegle Marmelos is very different, so that possibly our present Citrus trifoliata may be regarded as a connecting link between the two genera. *R. Irwin Lynch.*

Green Corn (see p. 146).—*A. N.* may perhaps learn in four or five years to detect the right moment to gather, but after more than twice that span I may confess to being not quite sure sometimes. But I do not "wait and see" as he has done—I simply "look and see" when the "silk" has withered back and the cob feels plump and the sheathing is fresh and green. A small tear or slit downwards to bring a few of the growing seeds into view will soon show whether the cob should be left awhile either to mature a little more or to ripen completely. After trying many sorts from our seedsmen, I got a satisfactory variety from Heinemann, of Erfurt, which I have kept going now for many years; though seeds ripen in the open now that the source is closed I always keep a few plants under glass for safety. I generally make four sowings for succession: this year the last sowing, I fear, will not make much else than rabbit food. In the late summer most plants do not seem to have grown well. *H. E. D.*

Large Peaches (see p. 160).—I recently saw several fruits of the variety Salwey grown by Mr. Brown in a Peach house in the garden of Mrs. Van Raalte, Brownsea Island, near Poole, Dorsetshire. The largest fruit weighed 15 oz., was well coloured, and for the variety was good in flavour. This tree is noted for the large fruit it has produced during the eighteen years it has been growing as a standard with a 4-feet stem; the branches are trained under the roof, so it is only a standard in the sense of its stem. Three years ago this tree produced a fruit weighing 10 oz., was 4 inches to 5 inches deep, and had a circumference of 14 inches. *E. Molyneux.*

The Late Mr. Arnold Duley.—It was with regret that I read in the *Gardeners' Chronicle* an account of the death of Mr. Duley, who served under me several years ago. While head gardener to the Grand Duke George of Russia he sent me several interesting letters, describing the climate, people, and other interesting details of the Crimea. He was a shrewd observer of men and conditions that he came in contact with. *T. H. Slade.*

Early and Late Peas.—May Queen and Chelsea Gem proved to be two of the best varieties here last spring. From plants raised from seed sown out-of-doors on a south border the second week in February, we were able to gather well-filled pods in the second week of June. The last named variety was sown the first week in July on a south border, and we are still gathering the second week in October good pods of the same. Autocrat and Michaelmas, sown the beginning of June, have been very prolific. *A. B. Wadds, Englefield Gardens, Reading.*

GLADIOLUS PROPHETESS.

THE beautiful new variety of Gladiolus named Prophetess, illustrated in fig. 67, was exhibited by Mr. J. S. Parker, Upton Cheyney, Bitton, at the meeting of the Royal Horticultural Society on August 27, 1918. An Award of Merit was awarded the novelty by the Floral Committee on the same occasion. The spike is exceedingly handsome, with bold flowers of cream white, blotched on the three lower segments with red dish brown.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

OCTOBER 8. *Rhododendron hybrids.*—Mr. E. Mezitt, Lamellen, St. Tudy, Cornwall, sent flowers of the beautiful deep red Rhododendron montigenum, raised by him from seed collected by Mr. G. Forrest. The plant flowers in April, and again in October as a rule.

Hybrid Buddleias.—Mr. W. van de Weyer, of Smedmore House, Corfe Castle, Dorset, sent flowering shoots of an interesting hybrid—Buddleia globosa ♀ × B. magnifica ♂. The flowers were in racemes of globose heads, purple in the bud, yellow to orange as they open, and very sweetly scented. The following note upon them accompanied the specimens: "I am sending here with some late flower trusses of some hybrid seedlings of Buddleia I have raised. They are, I think, interesting, as they are B. globosa (female parent) × B. magnifica (male parent). Some are the second generation of this cross seeded. The second generation shows no difference from the first. One gets just the same variations. The curious thing to me is the large percentage of pale coloured seedlings one gets, and I have not yet got an orange one. They all show B. magnifica leaves, except two, which have not yet flowered, and all flower at the same time, or later than B. magnifica, more flowering at the time of B. globosa. All are scented. I have also some crosses between Buddleia globosa (female parent) × Buddleia madagascariensis (male parent). These hybrids are not quite hardy. They flower very early, before B. globosa. All show the leaves of B. globosa, only as large as B. madagascariensis. All have large, orange ball trusses, like B. globosa, only the balls are larger, and none that has flowered so far is scented. I might add B. globosa × B. magnifica set seed freely naturally. B. globosa × B. madagascariensis does not do so, in fact, has never set a seed naturally, and I have been away in France, so have never pollinated the flowers by hand."

OCTOBER 22. On this date the meeting held at Westminster was fortunate in being attended by bright weather, and, further, there was a capital exhibition of interesting subjects and a fair attendance.

An extra batch of potatoes grown from seeds sown in July was especially interesting, as was also the Royal Horticultural Society's Food Production exhibit, consisting of about fifty cases of models illustrating the life histories of insect and fungous pests more or less common to garden crops; models of the processes of digging and trenching; models of a fruit grower, plant grower, of the Waley Orchard, and a garden path; a series of Harrod Boards; printing charts, and other exhibition features. This exhibit was the largest and most comprehensive the Society has displayed. Various parts of the country were represented in the Food Production competitions.

The Floral Committee granted six medals and the Veitchian Committee three medals, the Fruit and Vegetable Committee three medals, and the Orchid Committee a First-class Certificate and two Awards of Merit to Orchids.

During the afternoon Mr. ARTHUR W. SUTTON gave a lecture on "Summer Sown Vegetables as Secondary Crops."

Floral Committee.

Present: Messrs. H. B. May in the chair, J. W. Barr, John Green, G. Routh, George Harrow, John Heal, J. F. McLeod, Chas. Dixon, Arthur Dixon, Alex. Jennings, W. Howe, W. J. Bean, W. B. Cranfield, E. A. Bunyard, E. H. Jenkins, Chas. E. Pearson and C. R. Fielder.

Messrs. CHEAL AND SONS' group of trees and bushes, with brightly coloured foliage, was much admired. It contained many species of Berberis, Sorbus, Rhus, Acer, Viburnum, Liquidambar, Quercus and Pernettya. Nerine, were well shown by Mr. J. LEECH, Messrs. BARR AND SONS, and Mr. RITCHIE, the latter also staging *Delphinium Fargesii* with seven of its violet coloured fruits; Viburnum *theiferum*, brightly berried; Rosa *fargesia*, and a pink form of Rhododendron Thomsonii.

Among Messrs. BARR AND SON'S Nerines the blush pink Colleen and the broad petalled Mrs. Douglas were notable varieties, while in Mr. LEECH'S collection the variety Elegantissima was conspicuously good.

AWARDS OF MERIT.

Aster Beechwood.—A useful addition to the group of dwarf Michaelmas Daisies. It has the habit of growth and style of flower of Aster Beauty of Colwall, but the blooms are of a rich bright blue shade of colour. Shown by Messrs. BARR.

Pink Mrs. Donald Lloyd Group.—Large expansive and fragrant. Velvet has very large and rounded petals of a deep violet purple hue with a few deep markings at their bases. These latter are almost hidden by four small, petaloid stamens which are white, with violet lines, and form a distinct "eye" to the flower. The blooms are carried on long, sturdy stems. Shown by Mr. J. J. KETTLE.

Nerine Mrs. H. J. Elwes.—A very beautiful variety, with medium sized flowers of excellent shape borne on a compact but not too dense umbel. The segments recurve at the tips and the margins of the recurved parts are undulate. The colour is a dainty shade of shell pink with a ruffled zone of band that is not sufficiently distinctive to give a striped appearance. Shown by Messrs. BARR AND SONS.

Rose Brightest and Best.—A sturdy variety of the Nova Belgiæ type, multibranched, free flowering and graceful, and growing 4 feet to 5 feet high. The flowers are 2 to 3 inch across and have three rows of ray florets of a bright rosy mauve colour, those white at the base, while the disc centre. Shown by Mr. W. WELLS, JUNR.

Gipsies.

Silver Flag Medal.—To Messrs. H. B. MAY AND SONS, for Ferns and Caladiums, and Messrs. J. CHEAL AND SONS, for autumn coloured trees and shrubs, and Messrs. BARR AND SONS, for Dahlias.

Silver Banksian Medal.—To Mr. J. J. KETTLE, for Vases; Mr. J. LEECH, Gorrelsbury, for Nerines, and to the Rev. F. H. PEMBERTON, for Roses.

Bronze Banksian Medal.—To Mr. G. RITCHIE, for Hardy plants and Nerines.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart., in the chair, Sir Harry J. Veitch, Messrs. Jas. O'Brien, Lewis Richardson, W. H. White, R. A. Rolfe, Frederick J. Hanbury, Walter Cobb, W. J. Kaye, H. Ballantine, Sydney Morris, Fred Sander, H. Armstrong, Percy Kidd, H. T. Pitt, Colonel J. Wilson Potter.

AWARDS

First-class Certificate.

Odontoglossum crispum Ida Pagaden, variety of massive exception.—A grand flower in the product of Oak Mr. C. J. and A. McBEAN, Cooksbridge. And true of note and extreme size and their best forms of *O. crispum*. The flower is well made, shape with broad, overlapping sepals and petals. The inner parts of the segments are heavily blotched with reddish chocolate on a white ground. The broad lip is exquisitely marked, adds much to the beauty of the flower.

Awards of Merit.

Laelio-cattleya Linda C. Dawsonii var. L. C. Leeches, from Messrs. J. and A. McBEAN, Cooksbridge. A very desirable hybrid in which L. C. Hippodamia and C. Hardyana × L. tenebrosa plays a leading part, but the second introduction of *C. Dowiana aurea* gives perfect shape and fine substance. The sepals and petals are of medium rose with a slight gold shade. The lips are rose purple in front, with a yellow disc and it has orange lines running from the base.

Cattleya Iris var. Brigadier, Exquisite Perfection × *Mrs. Pitt*, from Dr. MARTIN LEGRAND, Beaulieu, Roehampton, Orchid growers, Miss Robertson. Medium flower of fine substance, the sepals and petals deep rose colour. The lips purple with a yellow disc and basal lines.

Grooms.

Messrs. SIDNEY LOW AND CO., Jarvisbrook, Sussex, were awarded a Silver-gilt Flora Medal for a group of excellently well grown and profusely flowered Orchids. Cattleyas, Laelio-Cattleyas and Odontoglossums predominating. Among the Cattleyas a fine specimen of the fragrant, white petalled *C. Lady Ingram alba*, *C. Amanda alba*, the bright yellow *C. Iris Butter cup* and some albinos were noted.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver-gilt Flora Medal for a excellent group of Odontoglossums, Cattleyas, Laelio-Cattleyas, and other Orchids. Among Odontoglossums "xanthotes" forms were specially attractive, and among the blotched forms *O. Doreen*, of large size and perfect shape, was remarkable. The new hybrid Brasso-Cattleya *Stamonar*, midseason (B. C. Mrs. J. Leemans and Sophronitis has yellow-buff sepals and petals and intense ruby coloured lip with deep orange-yellow centre.

Messrs. J. AND A. MCBEAN, Cooksbridge, were awarded a Silver Banksian Medal for a selection of hybrids. A new cross was recorded in Laelio-Cattleya Inez (*C. Warscewiczii* × *L. anceps* × *labiata*), a blush white flower with elongated, purple lip.

Messrs. ARMSTRONG AND BROWN, Tunbridge Wells, showed a select group of rare and home-raised Orchids. One of the most interesting was the pure white *Laelia purpurata purpurata alba*, which in point of size and shape is an improvement on the original. Odontioda Hector (Oda. Cordelia × Odm. crispum Raymond Crawshay) has a fringe and prettily marked flower. Laelio-Cattleya Pathin var. Domitian (L. C. Dominiana × *C. Dowiana aurea*), a well formed flower of rich colour, a pretty golden yellow form of L. C. Golden Wren, and the handsome Brasso-Laelio-Cattleya General French were included in the collection.

Messrs. FLORY AND BLACK, Langley, Slough, showed the pretty Sophro-Laelio-Cattleya Hannington, Langley variety, a splendid form of Odontoglossum waltonense Rex, the attractive Cattleya Mrs. J. Ansaldo, and Brasso-Cattleya Mossiæ *nigrina*.

Messrs. SANDERS ST. ALBANS, staged a small group, the best plants in which were Cattleya Lady Veitch var. Victory, a large, white flower with orange coloured disc to the lip, and *C. Gaskelliana* Triomphe de Bruges, one of the best dark forms with rosy mauve sepals and petals and purple crimson lip with fine gold lines from the base.

Mrs. BISCHOFFSHEIM, The Warren House, Stanmore (Orchid grower, Mr. W. H. Young), showed Brasso-Cattleya Digbyano-Mendelii alba.

De Meuleneire, Rochampton, sent Odontoglossum Meredithiæ Rossii rubescens × *crispissimum* with blush white flowers spotted with red brown, and *O. mirabile* var. Reyndii, a finely spotted form.

PANTON HALL, Esq., Ashtead Park (Orchid grower, Mr. W. H. White) showed Laelio-Cattleya Maquida, Ashtead Park variety, a very fine and richly coloured flower with dark ruby crimson lip.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Hurrell) showed the yellow Odontoglossum grande Pitturium.

Fruit and Vegetable Committee.

Present: Mr. Joseph Cheal in the chair, W. Bates, Owen Thomas, W. H. Divers, J. C. Allgrove, Edgar Beckett, A. Bullock, John Harrod, E. A. Bunyard and George S. Berry.

Messrs. SUTTON AND SONS' exhibit of vegetables raised from seeds sown in July attracted a great deal of attention from visitors who had no idea such excellent crops could be obtained fifteen weeks after sowing. Especially good were the Tender and True Cabbages, First Crop Cauliflowers, Favourite Carrots, White Gem Turnips and Matchless Cabbage Lettuces. (Silver-gilt Banksian Medal.)

Mr. H. CROST contributed a large collection of Apples, in which were handsome examples of Cox's Orange Pippin, Newton Wonder, Bramley's Seedling, Blenheim Pippin and Blue Pearmain. (Silver-gilt Banksian Medal.) Messrs. FELTON AND SON displayed some wonderfully fine Doyenne du Comice Pears, and Cox's Orange Pippin and Allington Pippin Apples, the latter brilliantly coloured. (Silver-gilt Banksian Medal.)

A small exhibit of first crop Carrots, Parsnips and Dutch Brown Beans, grown by girls from 7 to 17 years of age at St. Paul's School, Hammersmith, gained a Certificate of Appreciation.

NATIONAL CHRYSANTHEMUM.

OCTOBER 21.—No novelty was forthcoming at the Floral Committee's meeting at Essex Hall on the 21st inst.

At the meeting of the Executive Committee, held at the British Florists' Federation Offices, Covent Garden, in the evening of the same day, Mr. Thos. Bevan presided over a good attendance. Arrangements were made for the annual exhibition to be held on November 1. One new member was elected, and the interim financial statement showed a balance of £50 8s. 6d. An interesting discussion followed the formal business, and as an outcome of this a small committee was appointed to draw up a list of the best early flowering Chrysanthemums suitable for outdoor cultivation.

NATIONAL SWEET PEA.

OCTOBER 22.—There was a small attendance at the Annual General Meeting of the National Sweet Pea Society, held on the above date at the offices of the British Florists' Federation, Wellington Street, Covent Garden. The president, Mr. E. W. King, presided, and after the preliminaries had been disposed of he moved the adoption of the report. The motion was seconded by Mr. J. S. Brunton and carried. In the report special reference is made to the part taken by the Society in the Trafalgar Square Floral Fête in June last. At the Society's stand £131 14s. 10d. was taken, and this amount was supplemented on the occasion of the show at Westminster on July 2, and finally reached £197 13s. 4d. The president read letters from the Duke of Portland congratulating the Society upon its splendid help on behalf of the British Ambulance Committee, and stated that an ambulance was purchased with this money and is now in France, with a little brass plate on it notifying to all and sundry that its presence there was due to the National Sweet Pea Society.

The financial statement shows a balance of £7 17s. on a year's turnover of £169 18s. 10d., the chief items of expenditure being £89 9s. 9d. for printing and stationery; £50 secretary's salary; and £10 15s. 3d. for postages and telegrams. On the receipts side income from 1918 subscriptions stands at £99 7s. 0d.; 1917 subscriptions at £20 5s. 6d., and 1919 subscriptions £2 1s., all of which indicates continued interest in the Sweet Pea and its special Society.

Votes of thanks were accorded Mr. E. W. King (president), Mr. J. S. Brunton (chairman), Mr. E. Sherwood (treasurer), Mr. H. B. Tagwell (secretary), and Mr. R. Gluyas (auditor), all these officers were re-elected to their respective positions. The committee was re-elected, and four vacancies arising were filled by the election of Messrs. Dameram, Blundell, Forman and Peyman.

It is the intention of the committee to hold a Sweet Pea show at Westminster on July 1, 1919, and arrange a competition for the Society's dozen or so challenge cups.

CROPS AND STOCK ON THE HOME FARM.

THE PLOUGHING OF GRASS LAND.

IT is not known yet whether more grass land is required for cereal crops, although it is suggested that 1,000,000 more acres are needed. The matter will no doubt be settled by the various War Agriculture Executive Committees, which will arrange the quota for each county. I am in favour of breaking up poor pastures, as these are more remunerative as arable land.

The bulk of small crops are traceable to mismanagement. The occupier does not trouble to improve the land by draining or the application of suitable manures under the plea that labour is short. A want of inclination is often the main cause of neglect.

I do not think it can be doubted that at least 75 per cent. of the grass land ploughed up during the past two years has been a success, and this is a quite fair average under all circumstances. Many of those who do not wish to plough grass land say the crops following the second year are so inferior and that many more years must elapse before good pasture can be produced again. I contend that two years of superior cultivation will produce a good foundation for a future sward.

Oats may follow Wheat the second year if the Wheat crop was at all satisfactory. If not, Potatos and Mangold succeed admirably, and too many of the former cannot be grown, whilst Mangolds are always in demand by cowkeepers. In stiff, moist land Beans are a remunerative crop; indeed, there are plenty of possible and remunerative changes of crop if people have the will to try them in a progressive manner.

I am not in favour of ploughing up good grass land that produces heavy yields of grass or hay, because hay, milk and cattle are as much needed as Corn, but such land may be improved by the application of suitable fertilisers. The manner in which some advisory committees proceed in ordering certain fields to be ploughed is not in my opinion the best. To order a certain field to be ploughed against the advice and the offer of another by the occupier, who should understand what such fields are capable of, is the way to cause friction. A mutual agreement between the occupier and the committee as to the ploughing up of certain fields is the most likely method of success.

When an occupier agrees to plough a certain area of grass land he will plough that from which he is likely to get the best return, because any loss falls upon himself, except in certain cases where he can prove the loss was not due to his mismanagement. Cases for compensation need to be strongly supported by evidence.

The best time for ploughing grass land for cereal crops is a debatable point amongst cultivators. Some prefer to plough early enough to allow the turf to decay before the Corn is sown. In Southants we find success is more certain when sowing quickly follows ploughing. The argument for this plan is that if wireworms are in the turf they first work through the turf, and in the meantime the Corn is growing out of harm's way, because seldom, if ever, do wireworms affect the plant after it has made three leaves, but, when the turf has decayed, the wireworms are waiting for the newly-grown plant, and hence there is so much destruction. For Wheat and winter Oats the sowing should follow the ploughing up in October, or quite early in November. For spring sown Oats or Barley the ploughing should not be done until the end of February or early in March in southern counties.

The manner in which the ploughing is done is very important. Many farmers fail to have the whole of the grass therefore much of it grows between the furrows and long before summer is over the Corn crop is smothered by the grass and cannot do well. Every plough should have a skim coulter attached which cuts and turns over a small portion of turf in front of the main coulter, thus providing for the complete burial of the grass. If a heavy presser follows the plough the grass must decay, as air and light are absolutely shut out.—*F. Molyneux, Swanmore Farm, Bishop's Waltham, Hants.*

TRADE NOTES.

UNITED COUNCIL OF SEED TRADE ASSOCIATIONS.

SEEDS FOR ALLOTMENTS.—The Retail Committee is in general sympathy with the recent action of the Horticultural Trades Association, in connection with the scheme for the supply of seeds to allotment holders. Accordingly, it is deemed unnecessary to take separate action in view of the time and attention which has been devoted to the matter by the Horticultural Trades Association.

TESTING OF SEEDS ORDER, 1918.—A member reported that he had received the following letter from the Food Production Department with regard to the date of germination test:

DEAR SIR,—I am to refer to your letters of the 15th July and 15th August last with regard to Paragraph 2 m of the Testing of Seeds Order, 1918, which requires the month and year in which the test was made to be stated, unless such test has been made within six months from the date of sale or exposure for sale, and to say that the matter has come up for consideration before the Testing of Seeds Order Licensing Committee.

It is understood that your difficulty lies in specifying precisely the exact month of the test although it is known approximately within a few weeks. In such circumstances the Committee saw no objection to your stating the earliest known date, or declaring that the test had been made "since" a specified month and year.—Yours faithfully,

(Signed) R. J. THOMPSON,
For Controller of Supplies.

LAW NOTE.

GARDENER A MALE SERVANT.

AN interesting point respecting the employment of male servants was decided by the Oxted, Surrey, magistrates, when Mr. Edmund Howard Wilkins, Tatsfield, was summoned by the Surrey County Council Licensing Authority for keeping a gardener without a licence.

Defendant contended that although the man looked after the garden, with the help of a boy, he was chiefly cultivating food products, as he looked after two cows and forty head of poultry, and was not a luxury servant, but a labourer engaged on utility work. The prosecution urged that the man's principal occupation was that of a gardener. The bench took this view, and fined the defendant £5.

Obituary.

M. Pierre Guillot.—With regret I learn of the sudden death at Lyons, on September 27, of this distinguished French rosarian, the head of one of the oldest French firms of raisers of new Roses. Amongst other varieties his firm has given us La France, Mme. Falcot, Mme. Hoste, Gloire Lyonnaise, Mme. Leon Pain, and Comtesse d'Oxford. The third member of his family whom I had the pleasure of knowing, he had a great love of his favourite flower. He was a genial, kind-hearted man from whom any visitor to Lyons had a warm and attentive reception. *George Paul.*

ANSWERS TO CORRESPONDENTS.

GINKGO, OR MAIDENHAIR TREES.—*F. C.* The largest specimens of Ginkgo in this country is recorded in *Trees of Great Britain*, vol. I., p. 60, are (1) Kew Gardens—62 feet high, 10 feet 4 inches in girth in 1904; (2) Sherborne, Dorset—70 feet high, 7 feet 7 inches in girth in 1884; (3) Blaize Castle, near Bristol—68 feet by 9 feet 3 inches in 1905. See also Elwes, in *Gardeners' Chronicle*, October 27, 1917, p. 156, fig. 62. There are also large trees at (4) Frogmore, Windsor—74 feet high, 9 feet 3 inches in girth in 1904, and at Melbury (Dorset), Coldham Park (Kent), Longleat, and South Woodford. As these records were made some years ago it would be necessary to remeasure all these trees to ascertain which is now the tallest.

NAMES OF FRUITS.—*A. F.* Not recognised. Probably a local variety. *W. D. S.*, Herefordshire Pearmain.—*H. W. C.* c, Green Woodcock; k, Starmer Pippin.—*J. W.* 1, Reinette Tardive; 2, Beauty of Kent; 3, Barnack Beauty; 4, English Codlin; 5, William's Favourite; 6, Norfolk Stone Pippin.—*J. M. F.*, Apple Late Prince Albert.—*D. Pearman.* Claygate Pearmain.—In place of Cox's Orange Pippin you might try Allington Pippin, D'Arcy Spice, and Margil.—*Col. Northbrach.* 1, Duchess of Oldenburg; 2, Tower of Glamis; 3, Bismarck; 4, Golden Noble; 5, Mère de Ménage; 6, New Bess Pool; 7, not recognised; 8, Hanwell Souring.

NAMES OF PLANTS: *T. L. L.* The "Fern like" plant is Cycas revoluta; the broad leaved specimen is the Loquat, Eriobotrya japonica; and the other is probably a Protea species—send when in flower.

NOTES FROM KEW.—X.*

KEW is not by any means a dull place in October, and although the war has caused a cutting down of decorative effort, the permanent features keep the gardens alive. With its great wealth of trees and shrubs, autumn effects are always good at Kew, and as there is plenty of colour this year, the Beeches in particular being glorious, an afternoon in the gardens affords a feast of delight. There are numerous fruits, too, particularly Hips and Haws. I do not remember a year when the Hawthorn fruits have been more abundant, notwithstanding conditions which spoilt their relations, the Apples and Pears, in all parts of the country. The best of the Crataegus as shown fruited trees are Crus-galli, mollis, orientalis var. sanguinea, Oxyacantha var. Gireoudi pruinosa, punctata, prunifolia, and Downingii (syn. tomentosa).

Has anyone tried to cross Hawthorn with Apple or Pear? It might happen that, as with the Siberian Crab crossed with Apple, the mixing of Hawthorn and Apple would be a horticultural gain. I have not tasted a Crataegus fruit that is fit food for man, whatever our ancestors thought of them. I know that in America some of them are eaten; the Apple haw, C. aestivalis, for example, ripens early, the haws being fragrant, with a thick, juicy, acid flesh, and they are gathered in large quantities, to be made into preserves. Still, I would rather have the Cherry Apples, which are just as easy to grow as Hawthorns.

Pyracantha and Hawthorn might also be crossed with good results, if only to get the fruitfulness and lasting winter beauty of the Pyracantha into the Hawthorn. Of possible crosses there is no end, but they take time and are frequently failures, as every experienced breeder knows. The best garden races are pure with respect to species. There are exceptions. Roses and Rhododendrons, for example, but the rule is supported by Apples, Pears, Plums, Grapes—in short, I believe by all the fruits and all the vegetables, whilst among what we call flowering plants their names are legion. I suppose we must look upon species as only very pronounced varieties; still, practically all the great domestic races of plants are unitarian, so to speak, each group having sprung from one species.

A *Novice* writes disapprovingly of what I said in my last "Notes" with regard to the part Kew might play in the promotion of useful gardening as distinguished from the purely ornamental. There is room for both. The question is, should the great national garden interest itself in one and neglect the other—the other being at the present time the more important? The Mother Country has needs as well as the Colonies, for which Kew has done so much. As Dr. Lindley said in his report on Kew and its capabilities in 1840:—

"A national garden ought to be the centre round which all minor establishments of the same nature should be arranged: they should . . . all act in concert with it, and through it with one another, reporting constantly their proceedings, explaining their wants, receiving their supplies, and aiding the Mother Country in everything that is useful in the vegetable kingdom. Medicine, commerce, agriculture, horticulture, and many valuable branches of manufacture, would derive much benefit from the adoption of such a system. From a garden of this kind the Government would be able to obtain authentic and official information on points connected with the founding of new colonies; it would afford the plants there required without its being necessary, as now, to apply to the owners of private establishments for advice and assistance."

In this spirit Kew has worked for the past 70 years or so, and has accomplished great things. There is need for the same kind of help at home, and it would not be difficult for Kew, with all its resources and experience, to provide it without slacking off in other work of importance. The pathological department is a step in the direction of what is meant, its chief concern being with the diseases and pests of plants of economic importance, particularly fruits and vegetables grown in this country.

Kew professes to be a training school for gardeners, yet neither fruits nor vegetables are cultivated there, although the home gardener who has not been trained in their cultivation is like a man with one leg. In those times especially a gardener should know the best methods for the production of good fruits and vegetables. It is no answer that he can learn these things in other gardens, seeing that this applies to the other department of horticulture also. My dream is to see Richmond Park a school of forestry, and the Old Deer Park devoted to fruits and vegetables, and all combined to form the great national garden, Kew.

When Sir William Hooker was made Director of Kew in 1841, there were only about 15 acres devoted to collections of plants, and a few greenhouses. Before then, fruit and vegetables were grown at Kew to supply Buckingham Palace! What was then the fruit room is now Museum No. 1, the first museum of its kind to be formed, and the Orangery of that time is now a museum of timber. The former residence of the Duke of Cambridge is now devoted to a collection of woods and other exhibits, to illustrate British forestry products. "Imperial Caesar, dead, and turned to clay, might stop a hole to keep the wind away."

A *Novice* will probably tell me that what is required is not an essay on what Kew has been or might be, but Notes on the Kew of to-day. Well, progressive work has been somewhat hind red by the war. Still, something has been done to keep things moving and visitors interested. I have never seen the Conservatory (No. 1) gayer than it is now, and there are many interesting plants in flower, as well as those that are commonplace. On a recent Sunday afternoon, visitors crowded the house as though it had been the opening day at the Royal Academy.

Certainly the British crowd appreciates flowers. It was Mr. Chamberlain who complained to the late Director that the Palm House and Temperate House were dull because there were few flowers in them. Big houses will not grow flowers, so we grow them elsewhere, and put them in the big structures to please those people, the great majority be it said, who look for flowers in a garden whether it be outside or under glass. The Kew Ferns were never better than they are now, but they do not attract visitors. "Only Ferns," they say at the door, and generally they get no further. In the Palm House they are as a rule pleased with the big Palms and other tropical giants, but they have no eye for the collections unless there are flowers. There is a kind of picture hunting. They appreciate the Nepenthes, and the showy flowered Orchids. They also wonder at the Victoria regia, which is a kind of hippopotamus to them, but their great delight is when the Azaleas are in bloom and the Rhododendron Dell is at its best. Flowers, yes; plants, no. All the same, Kew is a place for healthy enjoyment to the many and a museum of interest and instruction to the few.

About 20 years ago Mr. Farini, of Westminster Aquarium fame, brought from the Kalahari Desert some bulbs of a Crinum which he presented to Kew. Some of them flowered, and Mr. Baker named them C. longifolium Farinianum (*Gard. Chron.*, June 25, 1887, p. 833). They were peculiar in having a long necked bulb and very long glaucous green leaves, the flowers being larger than those of the type and flushed with pink. Mr. Sharpe, of Westbury, Wiltshire, was at Kew recently, and he told me he had a Crinum with very long leaves which had grown well and flowered freely with him. He sent a leaf, and it measured 11 feet in length! I have never seen any Crinum leaf as long, but he informs me that the largest on the plant are

* Previous articles appeared in the issues of January 19, February 9, March 9, April 6, May 18, June 8, July 6, August 10, and September 21.

quite 2 feet more. He describes the bulb as "loosely built, 6½ inches in diameter, with a neck 20 inches long." It may be Mr. Farini's Crinum or it may be something new. Mr. Sharpe says that when the plant is in full growth the young leaves spring from a point over 5 feet from the ground. It will be necessary to keep the leaves in coils, as the tails of the Japanese long-tailed cockerels are kept. Mr. Sharpe has presented an offset of his plant to Kew. W. H.

ORCHID NOTES AND GLEANINGS.

SOPHRO-LAELIO-CATTLEYA WARNHAMENSIS.

A SUPERB flower, of brilliant colour, resulting from a cross between Laelio-Cattleya George Woodhams (C. Hardyana × L. purpurata) and Sophro-Laelio-Cattleya insignis var. Olive (C. Enid × S. L. Psyche) is sent by C. J. Lucas, Esq., Wareham Court, Horsham (gr. Mr. Duncan), with whom it now flowers for the first time. The variety has been pronounced by competent authorities who have seen it to be one of the best, if not the best, Sophro-Laelio-Cattleya in point of size and gorgeous colour. L.-C. George Woodhams is noted as a robust growing parent, and in this case the size, form, and depth of colour may be traced to that parent, although the small-flowered scarlet and orange S. grandiflora and L. cinnabarina, the parents of S.-L. Psyche, have undoubtedly imparted the glowing colour to the flower.

The flower, which is 6 inches across, has sepals 3 inch and petals 2 inches in width. The segments have an undulated margin and are of a rich white hue, from which spreads with increasing intensity towards the tips the glowing rose-purple tint which, with its darker veining, overspreads the other parts of the flower, as a rule, most with wavy margins and is of a rich crimson-purple colour with an orange base and numerous branched, golden-yellow lines. The coloring of the base of the lip is yellow, rather narrow, and showing in its shape the influence of the smaller and more bright-colored parent.

The rich colouring appears to be body colour rather than surface colour as in many hybrids.

ACANTHOPANAX LEUCORRHIZUM.

THIS interesting new Araliad (see fig. 68) is one of the most ornamental and reliable members of its family for the pleasure grounds and shrubbery borders. The plant figured as Eleutherococcus (Acanthopanax) leucorrhizus in *Gard. Chron.*, December 9, 1905, p. 404, is E. Simoni, which, among other differences, has smaller umbels of fruits, bristly hairs on both leaf surfaces, and more compact growth, hence it lacks the free and elegant appearance of the species under notice.

A. leucorrhizum is a deciduous shrub, gracefully arching in habit up to 7 or 8 feet in height, and probably more with age. The leaves are mostly in fives; the spherical umbels of flowers are interesting, but not conspicuously showy, and are developed in July. During September the bushes attain their greatest beauty, when laden with umbels of shining black fruits.

Seeds provide a ready means of increase. The plant thrives in most soils which are efficiently drained, with a preference for a light, friable loam.

A. leucorrhizum is a native of Central China.

Photograph by E. J. Watts.

FIG. 68.—FRUITS OF ACANTHOPANAX LEUCORRHIZUM.

Specimens were collected by Dr. Augustine Henry, but we are indebted to Mr. E. H. Wilson for its introduction to gardens in 1901. A. O.

NEW OR NOTEWORTHY PLANTS.

MESEMBRYANTHEMUM ACUTIPETALUM N. E. BR.

As this plant exists in some gardens without a name, and no description of it in English has yet appeared, the one which I give below may enable cultivators to identify it. I think it may possibly also exist in some gardens under the utterly erroneous name of M. aloides, for there are more than one species masquerading under that name in gardens, not one of them, so far as I have seen, being the true M. aloides, which I believe is not in cultivation. The plant described as M. aloides in all modern works is a very different thing to the true M. aloides, as I am demonstrating elsewhere, since those descriptions are all based upon the plant erroneously figured by Salm Dyck as being M. aloides, which was founded upon a Bechuanaland plant introduced by Burchell, whilst the plant represented by Salm Dyck is a very different species that was introduced later by Bowie from a totally different region.

M. acutipetalum belongs to the section Acuta, and is more nearly allied to M. diminutum, Haw., than to any other species, but is well distinguished by its very much shorter flower-stalks.

Plant dwarf, tufted, forming clumps 2-2½ inches high, including the flowers. Leaves 8-10 to a growth, ascending-spreading, ⅝-1½ inch long, 2½-3 lines broad and 1¾-2 lines thick at the base, viewed from above gradually tapering from the base to an acute apiculate apex, and in side view of nearly the same thickness throughout; flat above, keeled on the back, glabrous, smooth, dull greyish-green, densely covered all over the upper surface and back with dark green dots that are very pellucid when held against the light, and a row of similar but larger dots confluent into a well-defined pellucid line all along the margins and keel. Pedicel much shorter than the leaves, about 4-5 lines long, without bracts. Calyx unequally 5-lobed; lobes ascending-spreading, 3-5 lines long and 3-3½ lines broad, ovate, acute, or obtuse with a short dorsal point, margins membranous, green, dotted. Corolla 1¼-1½ inch in diameter, expanding in bright sunshine, scarcely scented; petals more than 100, in about four series, all closely overlapping and widely spreading, the outer 7-8½ lines long, half a line broad, the inner shorter and narrower, all linear, acute, bright pink, fading into white at the very base. Stamens numerous, collected into a somewhat conical mass, with the outer 3-4 series more or less barren, lax and erect or spreading, and gradually passing into petals; filaments pink, whitish at the base; anthers yellow. Stigmas 7, in the flower examined, arising from the conical top of the ovary, 1½ line long, erect, stout, subulate, acute, greenish-yellow.—M. acutipetalum, N. E. Brown in *Kew Bulletin*, 1903, p. 407.

When nicely in flower this is a very charming plant, flowering in September. It is a native of the region of Johannesburg, in the Transvaal and was introduced into this country in May, 1903. Its fleshy roots are used by the natives in the preparation of a fermented liquor called Khadi, a kind of beer for which they have a great liking.

It is somewhat odd that this genus does not find a greater amount of favour among plant-lovers than at present seems to be the case, for many of them are exceedingly beautiful and free-flowering. A good selection of those that have the best flowers make a very charming show. All they require is plenty of sunlight and air, and very little water. If grown in a more or less shady situation or in a damp atmosphere they do not thrive, but if placed in a sunny situation, repotted only when absolutely necessary (not every year), grown in a sandy-clayey loam more or less mixed with stones or broken brick, and the watering pot withheld as much as possible, they yield an excellent return in beautiful flowers of bright shades of yellow, pink, orange, scarlet, red, magenta, and white. *N. E. Brown, Mary Place, The Avenue, Kew Gardens.*

TREES AND SHRUBS.

LIQUIDAMBAR STYRACIFLUA.

Now that we are passing through the period of the autumn colouring of trees attention may be directed to the splendid hues of Liquidambar styraciflua, variously described as crimson and orange, or deep purplish-red, mixed with orange and some leaves wholly of the latter colour. There is a shapely tree of it, about 50 feet high, with a diameter of 12 to 14 inches near the base, though it tapers but little to a considerable height, close to Holland House, Kensington, where Mr. Dixon, the gardener, continues to add recent introductions to this London collection of trees and

shrubs. The soil at Holland House is heavy and inclined to clay, otherwise the tree might have been larger. It grows well in a loamy and fairly moist, though not waterlogged, soil. The first specimen of this tree to be introduced was planted at Fulham Palace in 1661 by the celebrated George London, who was then gardener to Bishop Compton. The young tree was sent home to him by Banister, the Bishop's missionary collector. The two stations are not far apart. When London published the first edition of his *Hortus Kewensis* in 1683, the tallest Lepidozamia in the gardens of London was 5½ feet at Syon House. Possibly this is the same tree that is now 45 feet high, measured in 1909. It was then stated to be the largest tree of the kind in Europe. I know of other trees of considerable size, but this is the only one of which I have any definite record. Loddiges' Catalogue, 1836, Hackney, N.E.

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lord C. J. SPENCER CHURCHILL, M.P., Ford Manor, Lingfield, Surrey.

Seakale.—A number of strong roots prepared last spring for forcing should be trimmed and set in the ground. Select the strongest roots for the first batch, trim the crowns and cut them to a uniform length of about 9 inches. Some of the roots will be long enough to make two crowns, but it is better to have only one crown to each root. Plant them in a cool house and keep them moist in the soil. Strong roots may be forced in any warm, dark room. A temperature of 50° at night and 60° to 65° by day is very suitable. It is best not to force seakale in the open ground. Cover the crowns of decayed leaves, and a few inverted pots should be placed over them to exclude the light. Some pots should be packed round with leaves and covered with fallen leaves, so that the roots may be lifted as required. Force in succession according to the season.

Preparing for Frosts. Owing to the mild weather which has prevailed most of this month, Broccoli has developed rapidly, and the plants of Early Cabbage and Coleworts will soon be ready for protecting. Such vegetables as these suffer from the effects of frost. Where single plants of border vegetables are required in addition to the protection of the quarters, the spare ones should be lifted with a ball of soil attached to the roots and planted in a cool house. Here they will continue to grow for a considerable time, and will be found useful for supplying vegetables during the resting season.

Preparing for Frosts. Owing to the mild weather which has prevailed most of this month, Broccoli has developed rapidly, and the plants of Early Cabbage and Coleworts will soon be ready for protecting. Such vegetables as these suffer from the effects of frost. Where single plants of border vegetables are required in addition to the protection of the quarters, the spare ones should be lifted with a ball of soil attached to the roots and planted in a cool house. Here they will continue to grow for a considerable time, and will be found useful for supplying vegetables during the resting season.

Globe Artichokes. Those protected by the ordinary Artichoke Antifrost Fillers should be examined. Cut off the frosted flower-stems and dead and worthless leaves. Ashes mixed in and around the stems are generally an efficient protection, but in Northern districts these may be supplemented with dry bracken to the depth of 12 inches. The roots must be covered, but not smothered, by the protecting material.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Trichopilia. Trichopilias flower at various times of the year, and for that reason their repotting is done at different periods; the best time is just when roots develop from the base of the new pseudo-bulbs. *T. suavis* is the handsomest species, and is most frequently grown, but *T. fragrans* and its variety *alba*, *T. coccinea*, *T. tortilis*, and *T. sanguinolenta* are all worthy of cultivation. Most of these plants grow best in rather deep Orchid pans suspended near to the roof-glass in a house having an intermediate temperature. *T. fragrans* thrives best during the summer on the stage in the cool Odontoglossum house. Whilst growing actively the plants should be afforded a plentiful supply of water at the roots, but when the soil soon gets dry it should be moistened, but not sodden, and more air given to ripen them.

Dendrobium. The majority of plants of the *Phalaenopsis* section and its varieties, *Vanda*, and the flowers may be cut for several weeks if kept in a moist atmosphere and untainted by [illegible]. Overwatering must be avoided, and the foliage of the plants [illegible] the species should be removed. When it has passed out of the sheath, it should be placed near the roof-glass in a light, airy compartment, does not fall before the [illegible] season of rest and roots should be [illegible] only sufficient to keep the [illegible] plump. Plants of *D. Phalaenopsis* [illegible] should after passing out of flower receive similar treatment. Evergreen Dendrobiums, such as *D. densiflorum*, *D. [illegible]*, *D. superbiens*, and *D. [illegible]* [illegible] should be [illegible] [illegible] [illegible]

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS**, 41, Wellington Street Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 45.7°

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, October 30, 10 a.m.: Bar 30.1, temp. 57°. Weather—Sunshine.

APPOINTMENTS FOR NOVEMBER.

TUESDAY, NOVEMBER 5—
Roy. Hort. Soc. Comm. meet. National Chrys. Soc. Annual Ex. at Drill Hall, Westminster. Hort. Club luncheon at 2. Whitehall Court at 1.15 p.m.

THURSDAY, NOVEMBER 7—
West Ham and District Hort. and Chrys. Soc. Ex. at the Conference Hall, West Ham Lane, Stratford (3 days).

FRIDAY, NOVEMBER 8—
Corn Exchange An. Chrys. and Fruit Show.

MONDAY, NOVEMBER 18—
National Chrys. Soc. Floral Com. meet., Essex Hall, Essex Street, Strand.

TUESDAY, NOVEMBER 19—
Royal Hort. Soc. Comms. meet.

Silver Leaf. The reference made in our issue of October 12 to the serious condition of Plum orchards due to Silver Leaf disease needs supplementing and emphasising, for there is no doubt but that this pernicious disease is increasing at a rapid rate. Not only is this the case, but it is also spreading to Apple trees, and although its progress on the Apple is less swift than on the Plum, it is probably only a matter of time for the fungus (Stereum purpureum), which is the agent of the disease, to make itself as fully and as disastrously at home on this fruit tree as it has done on the Plum. For it is to be remembered that parasitic fungi have a considerable power of adaptation, and can gradually so organise their attack as to break down defences which for a time sufficed to offer a strong resistance to attack.

One factor which we are convinced from personal observation contributes to the spread of the disease is the slight regard which is often paid to the disease in its early stage. This perhaps is due more than anything else to the curious aspect of the silvered leaves. In that stage there is nothing to suggest the deadly nature of the attack; and, moreover, the next stage, in which the branch dies back, is often not associated in the mind of the grower with the first, silvery stage. If he cuts away the dead branch at all, the grower often fails to cut it back far enough, and hence leaves the fungus to renew its attack. Even in the case of a dead tree which is cut down, growers often omit to grub up the roots, and hence, and particularly if the stock is the Mussel Plum, suckers are thrown up, every one of which is apt to be silvered, indicating that all unwittingly the grower has left a source of infection, from which the disease spreads to other trees. Nothing short of a crusade against this pest will suffice to rid our orchards and gardens of this pest, and, much as we dislike "Orders" and scheduling of pests, we are inclined to believe that steps in this direction will have to be taken before the disease can be brought under control. In the meantime, much can be done by spreading information as to the symptoms and mode of treatment of Silver Leaf disease. For of all common maladies of fruit trees, it is the easiest to recognise, and drastic treatment in the early stage, when the disease is confined to a single branch, may often save the tree. Once the infection is general throughout the branches, no remedy avails, and the only course is to leave the tree no longer to cumber the ground. Vigilance should be exercised, not only with respect to Plum and Apple trees, but also to other plants, since this disease is known to attack many different species common to gardens—among others, the Peach and Laburnum. Wherever found, it should be treated surgically, for there is no known medical treatment which can be counted upon to effect a cure.

National Chrysanthemum Society. — The Annual Floral Meeting of this Society, with competitions, will be held at the London Scottish Drill Hall, Westminster, on Tuesday, November 5, in conjunction with the meeting of the Royal Horticultural Society. We are asked to state that there is a misprint on the N.C.S. members' passes, and the date given thereon as November 8 should read November 5.

Ripe Plums on Growth of the Current Season. Mr D. D. ROBERTSON, Ashridge Gardens, Berkhamsted, Hertfordshire, sends branches of Victoria Plum bearing ripe fruits on the new shoots of the current year. A second crop of flowers is not unusual in the case of Apples, Pears, and Plums, but it is rare for the fruits that follow these abnormal blossoms to develop and ripen as in the case of those sent by Mr ROBERTSON.

Rev. J. H. Pemberton.—The many friends of the Rev. J. H. PEMBERTON will learn with deepest regret of the death of his sister, Miss HELENA PEMBERTON, which occurred at the Round House, Havering, on the 26th ult.

Spread of the Cotton Boll Weevil in the United States. From *The Agricultural News*, of Barbados, we learn that the Mexican Cotton Boll Weevil is spreading through the cotton growing districts of the Southern United States of America at the rate of 15,000 square miles per year. Infestation was first noticed in Georgia in 1915, and in 1917 the infested area was estimated at 44,500 square miles; in Florida the pest appeared in 1916, and spread so rapidly that in 1917 26,000 square miles were infested. Within 25 years the weevil has spread over nearly 500,000 square miles.

Control of the Prices and Distribution of Potatos.—On and after November 1 the whole of the Potato crop in England and Wales will be under the control of the Food Controller. Prices have been fixed by a Commission jointly appointed by the Food Controller and the Board of Agriculture, and these prices per ton to producers, free on rail, will vary for Grade I varieties from £5 15s. in the blacklands of Cambridge and Huntingdonshire to £8 in Sussex. But although the prices vary so much so far as the producer is concerned, there is a fixed general price which retailers will be allowed to sell at, i.e., 1½d. per lb. for Grade I varieties, and 1d. per lb. for all other varieties until the end of December; and 1½d. per lb. and 1½d. per lb. respectively in January. Retailers will be able to purchase their supplies at the fixed price of £9 per ton for Grade I Potatos, and £7 per ton for other sorts, such prices to include delivery to the retailers' nearest railway station. Wholesalers will buy at varying rates from the producers and sell to retailers at a flat rate, and they will act as agents to the Ministry of Food, and account to the Ministry for any difference between the buying and the selling price, after deducting commission (provisionally fixed at 7s. 6d. per ton) and necessary charges. To secure proper distribution England and Wales have been divided into twenty-one areas, eleven of which are "deficit" zones and twelve "surplus" zones; and through the Zonal Committees of the surplus zones, supplies of Potatos will be exported to the "deficit" zones, each of which is under the care of a Potato Control Committee. Growers may sell to registered wholesalers within their own zone, but to no one outside it. There are other minor points in connection with the Control of Potatos, but we need not detail them, as a leaflet for the guidance of retailers may be obtained on application to any Food Office, and a leaflet for growers and wholesalers may be obtained from the Ministry of Food or from the Zonal Committees. We may add, however, that Grade I Potatos are King Edward VII., Golden Wonder, What's Wanted, Langworthy, and Main Crop varieties. All others are in Grade 2.

The South African Fruit Industry.—At a recent meeting of the Western Province fruit growers in Capetown it was decided to form a co-operative selling society in the fruit industry. The proposal consists of the formation of a limited liability company, with a capital of £5,000, and fruit growers who are interested are asked to subscribe the capital. The object of this society, it is stated, will be to raise the standard of fruit placed on the markets. It is estimated that the organisation will be in a position to handle 40,000 tons of fruit in the course of a season, and this output, according to one member, is expected in the next fruit season. *Board of Trade Journal.*

Timber Trees for the Red Cross Funds.—An appeal is being made to owners of timbered estates in England and Wales for the gift of a single timber tree to be sold for Red Cross Funds. A fine Oak from Windsor Park has been promised by His Majesty the KING, and specimens have been offered or given by Lord CURZON, Lord CLIFDEN, Lord BOSTON, Lord GLENCONNER, Lord LILFORD, Lord POWIS, Lord REDESDALE, Col. B. RAYMONDSON, and Col. STOPFORD SACKVILLE. Messrs. RICHARDSON, timber surveyors, of Stamford, Lincs, have undertaken voluntarily the organisation of this scheme, and the felling and removal of the trees will involve no cost to the donors. It is hoped that very many trees will be donated, and as the Timber Controller has agreed to waive the "Fixed Price Order," a goodly sum should be realised.

War Items.—We learn with very deep regret of the death of Mr. JAMES GARDNER, gardener at Batsford, Gloucestershire. Mr. GARDNER was killed in action on the 6th ult., while serving with his regiment in Italy. His father was gardener to the late Sir JOHN ASTLEY, at Elsham Hall, for upwards of forty years, but has retired from active work. The late Mr. GARDNER started his business career in a bank at Huddersfield, but, disliking the confinement and monotony of the work, he soon tired of it, and elected to follow in his father's footsteps as a gardener. He was fortunate in having Mr. EDWIN BECKETT for his first master, teacher, and friend. No pupil could have had a better teacher, and few masters could have had a more apt and keener pupil. He left Aldenham after about three years, and entered on new duties at Eaton Hall Gardens, Chester. Here he came

under the tuition and discipline of Mr. N. F. BARNES. His advance was rapid and his success phenomenal, due, as he frequently and gratefully acknowledged, to the good training he received under Mr. BUCKELL and Mr. BARNES. After staying at Eaton for a few years he was appointed foreman to Mr. MULLINS, at Eastnor Castle Gardens. Here a misfortune far-reaching for him befell him. No garden is more renowned for fruit growing, and especially the cultivation of Grapes, than Eastnor Castle. From Eastnor he secured the position of gardener to the late Lord REDESDALE, at Batsford Park, Gloucestershire. Mr. GARDNER was only 24 years of age when he entered on his duties at Batsford. This position he held until he joined the Army about two years ago. He was one of the six who joined the Forces, content to take the rough and the smooth together with a light heart, making the best of the position cheerfully. He thoroughly fought, was helping wounded to the dressing station, when Lieut. BATESON and his party were caught in a heavy barrage, and he was wounded; but though wounded himself he went forward to the dressing station and brought back help for his men, thus showing splendid courage and self-sacrifice."

Driver H. BUZZARD, second son of Mr. H. G. BUZZARD, West Bark House Gardens, Heaton Mersey, was killed by a shell fired by the enemy on October 12. Prior to joining the Forces he was 22 years of age, and before coming was employed in the plant department at Eaton Hall, Chester. Much sympathy will be extended to his parents and his twin brother, Private G. BUZZARD, who had received wounds in France on April 14 last.

Pte. REGINALD MARTIN, only son of Mr. C. MARTIN, County Horticultural Instructor for the Isle of Wight, died of gas poisoning in

CELMISIA HOLOSERICEA.

THE genus Celmisia consists of 45 species, nearly all, with the exception of one, are natives of New Zealand. In this country they form one of the chief features of the mountain flora, the species usually forming a large proportion of the vegetation, especially in the Southern Island, where the mountain slopes and valleys are said to be whitened for miles by the abundance of the large Daisy-like flowers. All the plants are perennials, dwarf in growth, forming tufts of strap-shaped leaves of various sizes, either on short decumbent stems or without stems. Some species form wide, mound-like masses, whilst others grow as single small tufts. In this country, with the exception of one or two species, including *C. holosericea* illustrated in fig. 69, the cultivation of Celmisia has not been very

Photograph by C. P. Raffill

FIG. 68.—CELMISIA HOLOSERICEA: FLOWERS WHITE.

enjoyed his stay in Italy. Many of its beautiful gardens he was privileged to see and to enjoy, including La Mortola. With his death comes an untimely end to a promising career as a gardener and a good citizen.

—We have learned with very great regret of the death in action, on the 14th ult., of 2nd Lieut. JOHN BATESON, eldest son of Prof. W. BATESON, F.R.S., head of the John Innes Horticultural Institute, Merton, Surrey. Lieut. BATESON was educated at Charterhouse School and won an exhibition at St. John's College, Cambridge. He joined the Royal Field Artillery during the earlier part of the war, and in July last was awarded the Military Cross for conspicuous bravery. Although his battery was being heavily shelled on that occasion he twice went through an intense barrage to find a medical officer and assist the wounded; the same France early in October. He joined the Civil Service Rifles on the outbreak of war, was stationed in Ireland during the rebellion, and afterwards served on the Western Front and in Salonica, and was then transferred to Palestine where in the victorious advance to Jerusalem he won the Military Medal for conspicuous gallantry as a stretcher-bearer under heavy fire. Pte. MARTIN was only 24 years of age.

The many friends of Mr. and Mrs. ROGERS, Rendlesham Gardens, Woodbridge, will learn with regret that Pte. T. W. ROGERS, their only surviving child, was killed in France on October 12, aged 20. Previous to joining the Army in November, 1915, Private ROGERS served for two years in the gardens at Madley Manor, Farnborough, Hampshire, under Mr. ALLEN. He was for nine years engaged with his father in the gardens at Rendlesham.

successful. Although fresh seeds germinate freely the seedlings are somewhat difficult to manage, being very liable to damp off in their early stages. When first tried at Kew in quantity they were grown in a cold, span-roofed frame, and did remarkably well. Afterwards they were grown in a shady recess, where they flourished for a time and then began to fail. It may be that they are naturally short lived.

The specimen of *C. holosericea* illustrated in fig. 69 was growing in the rock garden at Kew on the shady side of Rhododendrons, having been moved there as a large plant from another position. It was planted in loose, well-drained soil consisting of fibrous loam, a little peat, and plenty of leaf-soil. It grew well for a few years, and then suddenly died after a severe winter. Young plants, in both shady and sunny positions, are now growing freely, and

promise to make good specimens. Many other species are in cultivation, one of which, *C. speciabilis*, was illustrated in *Gard. Chron.*, Feb. 9 last, p. 51. This plant is growing on a sunny slope and is apparently quite at home in this situation, though it received no protection during the winter. Species such as *C. Browni*, *C. Munroi*, and *C. coccinea* have been tried in shady positions, but do not make much progress, apparently suffering badly from the damp, foggy climate of our winters. It is intended to plant Celmisias at Kew in an open, sunny place, to see if they will succeed better in such a situation. *W. J.*

ON INCREASED FOOD PRODUCTION.

STORING ONIONS

This season I have adopted a simple plan for storing the Onion crop which I think is worthy of commendation to any who have a length of blank wall in a shed or loft. Essentially it is merely an application of the structure I described and figured a couple of years ago (*Gard. Chron.*, Sept. 3, 1916, p. 120, fig. 49). Some half dozen or so sticks, say, 9 feet long, stick according to requirements, and for each length of the trellis three stout stakes about 5 or 6 feet long are required. The only other need is three lengths of cord. The three stakes are leant against the wall, near the upper ends of each a piece of cord is attached, preferably by a rolling hitch, by which the uppermost stick is fastened horizontally; commencing with the cord the other sticks are hitched on below at a few inches distance from one another. The rack is then complete; there is no need to fix the supporting stakes in any way, as the weight of the Onions keeps the whole in place. The Onions are then hung on the horizontal bars in pairs by tying the leafage end to end with a half knot or twist. If the Onions have already been ripened out of doors on the similar support, one only needs to bring them in their pairs, and hang them on the trellis indoors. I know of no other method whereby the crop can be so quickly and satisfactorily accommodated with free ventilation for each bulb; moreover, the materials remain good for other purposes next season. *H. E. D.*

POTATO YIELDS COMPETITIONS

At Heston, near Hounslow, Middlesex, Potato competitions have been held each season for many years past. This year prizes were offered for the heaviest crops from 14 sets planted in a row 21 feet long and 2 feet 6 inches wide. Mr. F. Weston, Merivale Nurseries, won the premier award with 84 lbs., and Mr. S. A. Cragg was placed second with 81½ lbs.; other competitors followed with 76 lbs., 73 lbs., 69 lbs., 69 lbs., 65½ lbs., 55 lbs., 43 lbs., 36 lbs., 36 lbs., 35 lbs., 35 lbs., 35½ lbs. and 32 lbs. respectively, giving a total weight of 760½ lbs., or an average of 54·3 lbs. per 21-feet row, as compared with an average of 51·5 lbs. in 1917, 43 lbs. in 1916 and 53 lbs. in 1915.

Prizes were also offered for the heaviest crop of Onions grown in a 21-feet row, and here again Mr. F. Weston led; his crop weighed 35 lbs., the other competitors following with 31½ lbs., 26 lbs., 25 lbs., 23½ lbs., 20 lbs., 19½ lbs., 17 lbs., and 16 lbs. respectively. The average crop per row was 23·5 lbs.

POTATO YIELDS

At Potato competitions at Bonnesham, Berkshire, 14 rows yielded 10 cwt. 2 qrs. 21 lbs. 6½ oz. from 12 lbs. of seed. Each competitor received 1 lb. of seed tubers and was not allowed to plant more than 50 sets. The crop of the first nine in order of merit weighed no less than 6½ cwt. The first in order of merit was Mr. W. Hewett, Park Place, who from 25 sets lifted 162½ lbs.; 2nd, Mr. W. H. Chesterton, gardener to Captain Eyre, Wilmington Park, 125 lbs. 5 oz. from 50 sets; 3rd, James Stephens, gardener to Mr. W. H. Barber, Culham Court, 120 lbs., from 50 sets.

In the competition for the six heaviest tubers the awards were as follows: 1st, W. Tugwood, 11 lbs.; 2nd, W. Wallis, 8 lbs.; 3rd, W. Ward, 7 lbs. 15 oz.; 4th, J. Woodyatt, 7 lbs. 3½ oz.

MARKETING SURPLUS PRODUCE.

NEGOTIATIONS are on foot with a view to the County Marketing Societies in the various parts of the country supplying the Navy and Army Canteen Board with some of the latter's requirements in the matter of vegetables. In certain areas also it seems likely that the County Marketing Societies will utilise the existing industrial co-operative movement as part of their machinery. For example, in East Suffolk the Ipswich Industrial Co-operative Society, which has numerous country branches, will probably collect surplus produce at its depots for sale to members of the society in the town of Ipswich. Some such arrangement as this will economise in the cost of collection, transport, and general handling.

In Nottinghamshire a County Marketing Society is being formed with a capital of £1,000 (10s. shares), and about £300 has been already

THE LATE PRIVATE JAMES GARDNER.

(See p. 179.)

promised. A market organiser has been appointed, and the County Federation of Allotment Societies, with a membership of 7,000, is interesting itself in the scheme.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

American Blight (see pp. 50, 77, 92, 142).—The remarks of Mr. Molyneux and *R. C., Wilts*, prompt me to ask if certain kinds of Apple trees are immune from this pest which is rapidly spreading in many places. In this district some trees are badly infected, whilst others, viz., Keswick Codlin and Newtown Pippin, planted about the same time and growing in close proximity are quite free. In some old gardens there are many barren fruit trees which for years have only been breeding places for this pest, and in these days of fuel shortage would be better burned. *John Bates, Wrattord, Stow.*

Apples for Grass Orchards (see p. 154).—Considering the long experience of Mr. E. Molyneux, and his practical knowledge of fruit culture, I am somewhat surprised at the list of varieties of Apples he recommends for planting in grass orchards. Amongst the culinary Apples mentioned, the one I take exception to is Dumelow's Seedling. Wellington, for, while it is an excellent keeper and a fast rate cropper, the tree autumnalises as a bad grower, and except in favourable conditions is very liable to canker. I write with some knowledge of grass orchards in the West of England, and know of cases in which Wellington was planted by the side of Bramley's Seedling twenty years ago. The latter are fine spreading trees to-day, and have borne splendid crops of fruit, while the former are not much bigger than when they were planted. May I ask why Mr. Molyneux left Newton Wonder out of his selected list, as this is unquestionably one of the finest orchard Apples in cultivation, and it is being planted now more extensively in the West Country than Bramley's Seedling? In selecting varieties of Apples for planting in grass orchards, it is of the utmost importance, quite apart from the character of the fruit, that the tree should be a good grower, and no matter how good an Apple may be, unless it has capacity for making a large, vigorous tree, it is best left out of a grass orchard. For the reason here explained, I should not have included Worcester Pearmain in a short list of dessert varieties for grass orchards. *G. H. Hollingworth, Agricultural Organiser, County Education Office, Shire Hall, Gloucester.*

Mr. George Paul, V.M.H.—I was pleased to meet Mr. Paul at the recent Fruit Show of the R.H.S., and congratulate him on his golden wedding, which he and "his people" had been celebrating the previous day. I read the congratulatory notice in *Gard. Chron.*, and remembered that Reynolds Hole said something about my friend in his great book on Roses published in 1874. Here is what he said: "Mr. George Paul, 'the hero of a hundred fights,' advises 'that in planting the ground should be deeply trenched, and well-rotted manure be plentifully added. If the soil be old garden soil, add good loam, rich and yellow; choose a dry day for the operation, and leave the surface loose. Stake all standards, and mulch with litter to keep the roots from frost.' Well does the young champion sustain the ancient honours of his house, and none of his rivals grudge him his victory, because he never murmurs in defeat." This is worthy of repetition, because it is as true to-day as when it was written over 40 years ago! *W., Cuthbertson.*

Grow More Fruit (see p. 140).—A good plan for increasing the supply of fruit is to remove the large number of Privet hedges which partition the back gardens in many of the London suburbs, and in their place insert a few stout posts, 3½ feet long and 6 inches in diameter at the bottom, connected by No. 12 galvanised wire with a raddisent or winder at one end of each length, and a few galvanised staples. The posts should stand 6½ feet above the ground level and be fixed 12 feet apart; six wires can then be fixed 1 foot apart, with the lower strand 1 foot above the ground. Most kinds of hardy fruits may be grown against such fences, according to local circumstances; in most instances horizontally trained Apples would do well, and good trees would give a fair crop of fruit the second year after planting. The labour required would not be half of that necessary to keep the useless Privet in order, and a large addition to the fruit supply would be obtained without any decrease in the amount of ground used for growing vegetables. *W. H. Davis, Westdean, Hook, near Salisbury.*

September Rainfall.—*Market Grower* infers that September, 1918, was one of the wettest Septembers on record. Here, in South Hants, 7.52 inches of rain were registered, whereas in 1896 7.50 inches fell, and but seven dry days were recorded during the month. Records taken here over a period of twenty years show that the heaviest rainfall during the month of September was on the 24th, 1915, when 2.85 inches fell. As showing how closely alike is the rainfall in two adjoining counties, our figures during September, 1912, were 5.33 inches, while those in *Market Growers* district were 5.48 inches. During September, 1910, but 0.15 inch fell; in September, 1895, 0.42 inch, and in 1890 the record was 0.37 inch. During the twenty years total the total rainfall during September was 57.38 inches, an average of 2.55 inches. *E. Molyneux.*

Pruning Clematis.—I am in a state of confusion as to the pruning of the various sorts of Clematis, and the more works of reference I consult the more muddled I become. The following will illustrate my point. On p. 53 of *Teaching Plants*, by W. Watson, I read that the *C. lanuginosa* flowers "successionally on . . . summer shoots from July to October." On p. 55, that the Jackmanii sorts flower "successionally on summer shoots from July to October." Both, therefore, would appear to be of identical flowering habit. On p. 52 we are told that the pruning of lanuginosa forms "should take place in the months of February or March." Further down on the same page we are told that Jack-

manii, "being summer and autumn bloomers, flowering on the young or summer shoots . . . should be pruned by cutting back the summer growth each season," say in November." [Evidently this should read March.—EDS.] So far as I can make out, there are four principal types of Clematis which flower on the old or ripened wood, viz., Calycinae, Anemoniflorae, Azurae, and Floridae, and four which flower on the new or summer shoots, viz., Lanuginosae, Viticellae, Jackmanii and Paniculatae. I may also mention that on p. 49 of *Climbing Plants* it is stated that *C. montana rubens* flowers in May, whilst on p. 52 it is described as autumn flowering. *Herbert Allen.* [The type flowers in May, the variety *rubens* several weeks later, but both may produce occasional blooms in autumn.—EDS.]

Planting by Worms.—I have been much interested in the earth-worms in my small garden in South Kensington. Three weeks ago I clipped off some Pelargonium (Geranium) leaf stalks, about 5 inches long. In a day or two I was surprised to find one of them standing upright in the flower bed, as it planted there. More than that, in a few days more the buds expanded to a perceptible extent. To-day, after three weeks, the stalk is still erect, fleshy, and the buds firm and fresh-looking, reddened. No doubt the worm, after beginning interment found the stem to be not yet quite without the elements of life, and the leaf to be not eatable or fit for storage purposes. At a more favourable season no doubt the buds would have fully expanded. Twigs cut from my hedge I have found "planted" in exactly similar way and left thus for the same reason, as they continued green, with leaves unaffected, for some time. The butt end is always drawn-in first. No doubt these twigs, if planted in this way in the proper season, would have rooted. *Thos. S. Carson.*

SOCIETIES.

NATIONAL CARNATION.

OCTOBER 19.—The annual general meeting of the National Carnation Society, Southern Section, was held in the Library of the Royal Horticultural Society on Saturday, October 19. The report and statement of accounts were submitted, the latter showing a balance in hand of over £30.

The annual floral meeting for 1919 was fixed for July 15, in conjunction with the fortnightly meeting of the Royal Horticultural Society, in the Drill Hall, Buckingham Gate, Westminster. The hon. secretary is Mr. J. J. Keen, 54, The Avenue, Southampton.

SOUTHAMPTON ROYAL HORTICULTURAL

OCTOBER 15 16.—A food production section was held by the Southampton Royal Horticultural Society on the foregoing dates on the Royal Pier, Southampton.

The vegetables in all classes made a good and amateurs reached a high standard of excellence. Potatoes, Onions and Cabbages being most prominent. The Royal Horticultural Society sent a special deputation to the exhibition with power to award medals, and the number of such honours was unusually large.

The R.H.S. Gold Medal was awarded to Messrs. Toogood and Sons for a display of vegetables, and W. H. Mayes, Esq., Sommon Park, for Mr. G. Ellwood was awarded two Silver and two Bronze Medals for collection of fruit, Grapes, a collection of vegetables, and Onions respectively. The Duke of Wellington was awarded a Silver Medal for a collection of fruit, which also won the Victoria Memorial Trophy, and a Silver-gilt Medal for a display of vegetables; and to Ellis, Lord Swaythling was awarded a Silver Medal for a collection of fruit. Other awards of the R.H.S. were as follows:—

Mr. H. Broom, Barton Peveril, Silver-gilt and two Bronze Medals for collections of vegetables. Mr. S. F. White, Eastbrigh, three Bronze Medals for collections of vegetables; Mr. W. Smith, allotment holder, Rockstone Road, Bronze Medals for a collection of vegetables and dish of Potatos respectively; Mr. F. M. Voules, Sholing, a Silver-gilt Medal for vegetables; Mr. J. Liddell, of Shirley, Bronze Medal for a dish of culinary Apples; Mr. D. Wilton, Bronze Medal for culinary Apples; Mr. E. Palmer, Silver-gilt Medal for a collection of vegetables; and Mr. J. Enticott, Eastleigh, Bronze Medal for a collection of vegetables.

The Challenge Cup offered for the highest number of points was won by Mr. S. T. White; Mrs. Tofield, of Westend, secured the Mazawattee Cup offered for the best Chrysanthemums.

There was an excellent display of non-competitive exhibits, including a particularly instructive model of wheat, as well as a display of insect pests by the R.H.S. A Gold Medal was awarded to Messrs. Laxmans for a display of hardy shrubs. A Silver-gilt Medal was awarded to the Gas Company for bottled fruit and dried vegetables. Mr. W. C. Robbins, Bitterne Park, displayed the results of trial cultivation of various varieties of Potatos, and was given an Award of Merit.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

OCTOBER 14.—The fortnightly meeting of this Society was held in the R.H.S. Hall on the 14th inst., Mr. C. H. Curtis presiding. One new member was elected. One member was allowed to withdraw the sum of £18 19s. 11d. from his lapsed account. The Army forms of the late Lance-Sergt. H. Hawkes, Pte. N. V. Heath, and Lance-Corporal F. G. Wills, were received, and also the death certificates of two other deceased members, and the sum of £75 0s. 0d. was passed for payment to their respective nominees. The sick pay for the month on the ordinary side amounted to £52 7s., and on the Sick section to £29 17s. 6d., while the maternity benefits came to £7 10s. One member was assisted from the Orphan Fund, and one member was relieved from Distress Fund for life.

CROPS AND STOCK ON THE HOME FARM.

BASIC SLAG ON GRASS.

[illegible] to operate upon [illegible] pastures and meadows and farmyard manure [illegible] will [illegible] basic slag at the rate of 2 cwts. per acre. These [illegible] were carried out in accordance with [illegible] have since been [illegible] results [illegible] various seasons [illegible] speaking in general terms. Even on the poorest [illegible] a dressing of basic slag, followed in the autumn, as it should be, affects the growth of the grass and induces clovers of various kinds to spring up where clovers were not known before, is a mystery. My view is that the soil is getting more to the acid and the basic slag corrects the constituent necessary for the germination. In sandy soil basic slag does not act so quickly. Where there is much clover, moles love slag to eat, great assistance to the moles, additional sweet herbage, but it is well to allow the sheep to graze on the field for at least six weeks after the slag is applied.

Pastures regularly used for cows or horses, where continual feeding is necessary, can be improved by the use of basic slag and agricultural salt in alternate years.

CABBAGES.

One must [illegible] to refer to the [illegible] owing to the great value for feeding purposes especially [illegible] these are many concentrated foods are unobtainable. The 6 degrees of frost on Oct. 8 completely spoilt the Maize that remained, during the Cabbage crop doubly valuable to the cowkeeper as a means of increasing not only the quantity but the quality of the milk. Breeding sows have [illegible] on Cabbages and [illegible] they pick up in the fields, as meal or bran is almost out of the question for them. With the sudden absence of the Maize, which [illegible] a valuable green food for cows, I do not [illegible] to advise [illegible] Cabbages now that the grass has deteriorated in quality owing to heavy rains. Early Drumhead Cabbages sown on April 15, and planted 2 feet apart are yielding as much as 30 tons per acre. In any of the heads weighing 12 lbs. each. The ground was never hoed, and no artificial stimulant was given, but 15 tons of farmyard manure was ploughed in during the autumn. I mention these points to show how easily Cabbages are produced. The Late Drumhead Cabbages are now hearting, and will last until well into February. I shall hesitate to grow Maize in future, as early frosts in October have killed the crop two years in succession.

HEDGES.

The present is a suitable time to cut down, trim, and trim hedges, as the current season's growth has not yet fully matured, and will cut [illegible] now than after Christmas. High hedges round arable fields are a mistake, as is [illegible] the state of the corn near the hedges [illegible] so many weeks owing to the difficulty of the soil and to drying quickly after showers, or even heavy dews. Apart from the difficulty of drying the corn or hay, high hedges harbour sparrows, which are increasingly troublesome, and do much damage to all cereal crops, not only as the grain is filling out and ripening, but [illegible] after it is cut.

In the case of pasture fields hedges 6 feet high provide valuable shelter for cattle, but in the ordinary arable fields, where cereals, roots, and hay only are grown, I do not favour a hedge more than 4 yard high at the most, which is sufficient to prevent cattle or sheep, when driven along the road, breaking through into the fields. Much valuable space is often occupied by tall, wide hedges; the ground would be much better occupied with crops. Where an overgrown hedge of any kind exists, and it has become thin at the base, and is not immediately required as a protection against cattle, it is better cut down to within 6 inches of soil; from this base stout, [illegible] shoots will spring, and at these are cut back in the autumn to within 1 foot, a thick, useful hedge will be obtained again quickly. Where however, a fence is required at once, it is better to "lay the hedge by splaying the stout portions a foot high; simply take off a slice a few inches long, give that portion a crack across so that the piece will bend and lay it in any position required. Quite a thick, stout hedge may be made thus, and with subsequent growth from the laid in portions the hedge will be quite [illegible] proof. All this, in addition to trimming and making up the banks and clearing the watercourses is work that can be carried out during the winter.

I fear too little attention is paid to ditches and drains around fields; if these details were regularly attended to we should hear fewer complaints about the unsuitability of certain fields for arable culture.

Overhanging boughs of trees in hedges around fields should be attended to; where these extend too freely the various crops are reduced in bulk as well as in quality. *E. Molyneux.*

TRADE NOTES.

THE SUPPLY OF SEED POTATOS.

The President of the Board of Agriculture having given careful consideration to the question of the distribution of seed Potatos of the 1918 crop in England and Wales, has decided that the Board shall leave the supply to the ordinary trade channels.

It will be remembered that the scheme of distribution by the Food Production Department was introduced in the season 1916-17 when the supply of "seed" was extremely limited, and in order to overcome the difficulties of the allotment holder and cottager in obtaining suitable Potatos for planting. This scheme was put into operation again in 1917-18 in order to demonstrate further the value of change of "seed."

Mr. Prothero is of opinion that the objects which the Department had in view have now been secured, and that the prospects of the present Potato harvest yielding an ample supply of good "seed" are such as to remove the justification for the amount of Government interference involved in the distribution of "seed" by Agricultural Executive Committees during the coming season.

An Order relating to the sale and distribution of seed Potatos will shortly be issued by

the Ministry of Food, by which maximum prices (a) paid to the grower, and (b) charged by wholesale and retail dealers will be fixed for different classes and varieties. Under the Order it will be possible for small growers to obtain their requirements either direct from the grower or through ordinary trade channels. In any case where a society or group of small growers finds difficulty in obtaining supplies the Department will be prepared to give information as to reliable sources.

PROHIBITED IMPORTATION OF NURSERY STOCK INTO THE UNITED STATES.

A PROPOSAL is on foot to establish a measure prohibiting the importation of all nursery stock into the United States of America after June 1, 1919, fruit trees, seedlings, and Rose stocks alone to be excepted. It appears that this proposed legislation has the support of the Federal Horticultural Board of the U.S.A. Department of Agriculture, and of the Legislative Committee of the American Association of Nurserymen

Obituary.

E. J. Allard.—There will be many in the gardening world who will grieve to hear that Mr Edgar John Allard, Superintendent of the John Innes Horticultural Institution, died on October 23, 1918, from pneumonia after influenza, in his 42nd year

He was in many ways an exceptional man, and his services in organising the various lines of work, scientific and practical, in progress at the Institution, were of very high value. He had exactly the qualities needed for the conduct of experiments, the results of which in many cases can only be reached after a long period of years. He was instinctively accurate, acquiring without difficulty the habits of clean, precise manipulation and recording which are essential to success in such operations. He came of a Maidstone family, and as a young boy was started in the building trade, but even at that early age his tastes were so clearly marked that he ran away and went to work in a garden unknown to his parents. He was a born gardener. Trained in the hard mill of grower's work, he passed through several nurseries, notably that of Messrs. Sander. He then went as a young gardener to Kew, serving in various departments, and from thence to the Cambridge University Botanic Garden, where he was Mr. Lynch's right hand man for several years. As he grew older he turned more and more to the scientific side of horticulture. He had a sound knowledge of British plants, and had given much spare time to field botany, but his main interest was in the species of plants mostly cultivated in botanic gardens, with which he had a very wide range of practical acquaintance. Gifted with what may be called a natural sympathy for plants, he became a most skilful cultivator, and was successful with many notoriously difficult subjects. His plants almost always thrived. In an unusual degree he had developed the faculty of being aware whether he did or did not know a thing—one of the highest manifestations of memory, which makes the statement of such a man implicitly reliable.

Apart from the work that he did in carrying out the ideas of others and maintaining their experiments in good order, he did a great deal of plant breeding on his own account. Among novelties which he raised, a fine series of hybrid Calceolarias of extraordinary beauty will long keep him in remembrance. Several of these were handed over to Messrs. Sutton and Sons, and were a feature of the Chelsea Show in 1914, receiving a Silver Banksian Medal and a Certificate of Appreciation. In the following year another Banksian Medal was awarded to a further and very remarkable series of forms raised by crossing Calceolaria cana with certain garden varieties. Besides the greenhouse series, one named "John Innes," derived from *C. plantaginea* × *C. polyrrhiza*, is remarkable as being perfectly hardy, having survived the last three winters in open ground. A beautiful hybrid Passiflora, and also a Nepenthes, both of which he raised at Cambridge, have also been described under his name. At Merton he took great interest in the young men and boys who came under him. Knowing the difficulties of others as only those who have taught themselves can do, he was an excellent teacher, and perhaps enjoyed talking and demonstrating to his young gardeners more than any other part of his work.

As the conditions of the war became more severe and his staff was depleted, his responsibilities increased. Suffering already somewhat in health, he would not relax his devotion to his work, and refused proper rest, though it was evident to his friends that the strain was telling on him, and his powers of resistance impaired. Many felt the charm of his personality, and he will be greatly missed by various bodies, especially by the Scientific Committee of the Royal Horticultural Society, the Committee of the United Horticultural Benefit and Provident Society, and the Committee of the Kew Guild, of which he was a diligent member. *W. Bateson.*

The funeral service was held at Merton Park Church on Monday, the 28th ult. Amongst those present were the widow, her brother, Gunner Marshall, R.G.A., Professor W. Bateson, Director, and Mr. G. W. Gill, foreman of the John Innes Horticultural Institute; Sir David Prain, Director of Kew Gardens; Mr

THE LATE E. J. ALLARD.

A. J. Bruce, of the Board of Agriculture; Mr. W. Hales, Chelsea Physic Gardens, representing the Council of the Royal Horticultural Society; Messrs. A. Osborn, W. Taylor, and W. Lavender, representatives of the Kew Guild; Messrs. A. C. Hill, W. Winter, W. Wesker, and Penton, of the United Horticultural Benefit and Provident Society's Committee; Mr. J. Bintner, Imperial Institute; and Mr. A. C. Bartlett, representing the *Gardeners' Chronicle*.

Answers to Correspondents.

BEST FRUITS FOR A SCOTTISH GARDEN: *H. P.* Apples for cultivation as standard trees in Scotland as recommended in *A List of Most Desirable Varieties of Fruits*, published by the Royal Horticultural Society, are, for cooking: Lane's Prince Albert, Ecklinville, Lord Derby, Stirling Castle, and Bramley's Seedling; for dessert, Cox's Orange Pippin, Lady Sudeley, Wingston Pippin, James Grieve, and Beauty of Bath. Cherries, trained to a wall, May Duke, Early Rivers, Florence and Governor Wood. Pears, trained to a wall, Williams' Bon Chrétien and Doyenné du Comice, with either Jargonelle, Conference, Louise Bonne of Jersey, or Marie Louise as a third variety.

GAS-LIMING VACANT GARDEN GROUND: *E. H.* Gas lime is an excellent soil cleanser, but as it is as destructive to plant life as to insects, including slugs, care is needed in its use. Where land is quite vacant and not needed for cropping for some time to come, a dressing of gas lime may be desirable, both for ridding the soil of slugs and other pests, and for cleansing it of the fungus that causes club-root. A ton of fresh gas lime per acre is sufficient, provided it is used as fresh as possible. If exposed to the air for any considerable period gas lime loses much of its disinfecting power. Spread the gas lime evenly, and break the lumps as finely as possible; let it lie on the surface for a week or two and then fork it into the ground. Six weeks should elapse between the time of application and the time of sowing or planting the treated soil.

GRAPE ROT: *J. E. J.* The disease known as Grape Rot is caused by the fungus named Gloeosporium ampelophagum. It may be kept in check by dusting the vines with flowers of sulphur and quicklime during the period of growth, at intervals of ten days. On the occasion of the first dusting use sulphur alone; for subsequent applications add a little quicklime and increase the amount of lime with each dressing, until lime and sulphur are in almost equal proportions, but always use a little more sulphur than lime. Vines weakened in constitution by a bad rooting system or cultural errors are always more liable to disease or insect infestation than those in robust health.

LILY-OF-THE-VALLEY: *M. P.* Out door beds of Lily-of-the-Valley should receive a liberal dressing of rotten manure each year in autumn as soon as the leaves have decayed. If the soil has been washed away so as to leave the bases of the crowns bare, a dressing of rich soil, sifted, applied before the manure, will greatly assist the plants. Old potting soil, with the addition of leaf-mould, will provide material for a suitable top dressing. In the early summer, as the leaves are developing, occasional waterings with liquid manure will assist that development, and consequently react upon flower production. In this case free foliar development is essential to the free production of fine spikes of flowers. Similar treatment should be followed with Lily-of-the-Valley grown in pans and tubs, but owing to the limited amount of soil in these receptacles more frequent manurial dressings should be provided to maintain robust growth.

NAMES OF FRUITS: *P.* Beurré Bosc.—*N. E. J.* 1, King of the Pippins; 2, Waltham Abbey Seedling; 3, Ross Nonpareil; 4, Hollandbury; 5, American Mother; 6, Claygate Pearmain.—*C. H.* A seedling variety; not recognised.

NAMES OF PLANTS: *R. A. C.* Spiraea japonica alba.—*L. B. E.* Stephanandra Tanakae.—*T. T.* Lomicera sempervirens.—*O. B. J.* 1, Ficus Parcellii; 2, Leycesteria formosa; 3, Pteris semipinnata; 4, Todea superba.—*L. E. S.* 1, Amelanchier canadensis; 2, Polygonum baldschuanicum; 3, Berberis Thunbergii; 4, B. vulgaris; 5, B. Hookeri.—*A. J.* 1, Prunus lusitanica (Portugal Laurel); 2, Laurus nobilis (Bay Laurel); 3, Jasminum officinale; 4, Olearia macrodonta; 5, Veronica speciosa var.; 6, Caryopteris Mastacanthus.—*L. G. Pike.* Gleditschia triacanthos (Honey Locust). A native of the United States, and hardy in this country.—*F. E. B.* Eupatorium Weinmannianum.

STOCKS FOR FRUIT TREES: *J. W. W.* Nurserymen who make a speciality of fruit-trees may be able to supply you with the various kinds of stocks you need. Names and addresses of firms to whom you could apply will be found in our advertising columns.

AUTUMN CROCUSES.

COMPARATIVELY few gardens seem to contain many species of autumn flowering Crocus, and yet the individual flowers are so beautiful and the cultivation so easy that it is surprising they are not more generally grown. Here, in my night, sandy soil, the difficulty is not to grow them, but to prevent them coming up in all sorts of unexpected places, for they seed themselves very freely, and, in addition, some species form tiny offsets which get left in the soil when the corms are lifted to grow to flowering size, and send up their bloom among any plants that have been planted above them.

The first to flower in this garden, and the most ubiquitous for the two reasons mentioned above, is C. zonatus, the well-known species from the mountains of Cilicia and the Lebanon. It derives its name from the bright golden ring that encircles the throat of the flower on the inner side of the segments. This Crocus forms immense flat corms often so much as an inch and a half in diameter. Each corm throws up several flowers in succession, so that the display lasts practically throughout September and October. The colour is pale pinkish lilac, though specimens occur in which the colour is so pale that the flowers appear by contrast with their neighbours to be almost white.

Another species, which is even more vigorous than C. zonatus, though a little less liable to spread by leaving minute offsets in the ground, is C. speciosus, from Persia, Asia Minor, and the Caucasus. It is one of the tallest and largest of Crocuses, and the red, tassel-like style forms a striking contrast to the blue-purple flowers, which bear conspicuous darker veins. In most forms the throat of this Crocus is white or only very faintly tinged with yellow, but there is a very beautiful pure white form in which both the throat and the style are golden. A group of flowers of this albino form wide open in the sun, with the pointed petals extended nearly horizontally, is a very cheering sight in September. There is another white form with less pointed segments faintly veined with lilac, but this, in my experience, is neither so vigorous nor so beautiful as the pure white form.

C. speciosus has yellow anthers and pollen, but I find occasionally that specimens appear which are to all intents and purposes C. speciosus except that they have white anthers and pollen. These must apparently be hybrids of that species, and either C. zonatus or a third species, C. pulchellus, which, though it has been in the garden here for a number of years, never seems to spread or increase with the vigour of the other two. It is distinguished by the clear, pale bluish colour of the flowers, with five conspicuous veins on the inner segments. The anthers are white and the filaments conspicuously hairy. It is a native of the Balkans and the neighbourhood of Constantinople, and it would be interesting to know under what conditions of soil or cultivation it grows vigorously, for with Mrs. Grimwood it was "of robust habit" and "increased freely from seed very freely."

FIG. 70.—CROCUS BORYI MARATHONISIUS: FLOWERS WHITE.

Another species which also declines to do really well in my garden is C. iridiflorus, which is perhaps the most distinct of all Crocuses. It is a Transylvanian plant which was well described on p. 158. It is remarkable for the small size of its inner segments, which are barely half the size of the outer series. The type is beautiful, but even more striking is the pure white albino form, in which the style-tassel is also white. Mr. Bowles told me once that this is one of the Crocuses that requires a relatively cool position where its foliage will not dry off too early in summer, but my difficulty is to find such a position which will also be open to the midday sun in September, so that the flowers may be induced to open and to display themselves to advantage.

September is also the flowering time of the Pyrenean C. nudiflorus, with large, tall-growing flowers of a clear purple. This species is said to have become naturalised in some of the N. Hand counties of England and is remarkable for its curious habit of sending out stolon-like growths which form new corms at a distance from the parent corm. The plant does not grow very vigorously with me, and it would not be surprising to find that it needs a soil which remains moist even in summer, for this seems to be the case with many plants which are natives of the Pyrenees, where underground moisture appears always to be abundant in the soil.

On the contrary, C. medius, from the Riviera, grows well here, and the large, deep red style forms a striking contrast to the deep purple of the flowers. C. medius flowers early in October, and is a sturdy, vigorous species.

All the foregoing Crocuses have the disadvantage that the flowers appear above the ground while there is still no vestige of the foliage apparent. This only develops later. By mid-October, however, several species begin to flower, of which the leaves are at any rate partly de-

veloped when the blooms open. Of these the first to flower in my garden is C. hadriaticus, from Albania and Greece. It has white flowers with rather pointed segments and a long, narrow scarlet style like that of C. sativus, to which it appears to be closely related. The corms of the two species are very similar and are enclosed in soft fibres which form a tuft of hairs at the apex. Maw says that there is no satisfactory character to distinguish this species from C. sativus except the colour of the flowers, and, since colour is usually not a good specific character, it is no surprise to find that pale lilac-coloured forms appear among seedlings of the ordinary white C. hadriaticus.

C. sativus is a richly coloured species, with lilac-purple flowers, of which the throat appears much darker owing to numerous dark veins. The style is very long and narrow and of a bright red colour. The corms must be large and vigorous for flowers to be produced. In the resting state they are surmounted by a tuft of soft

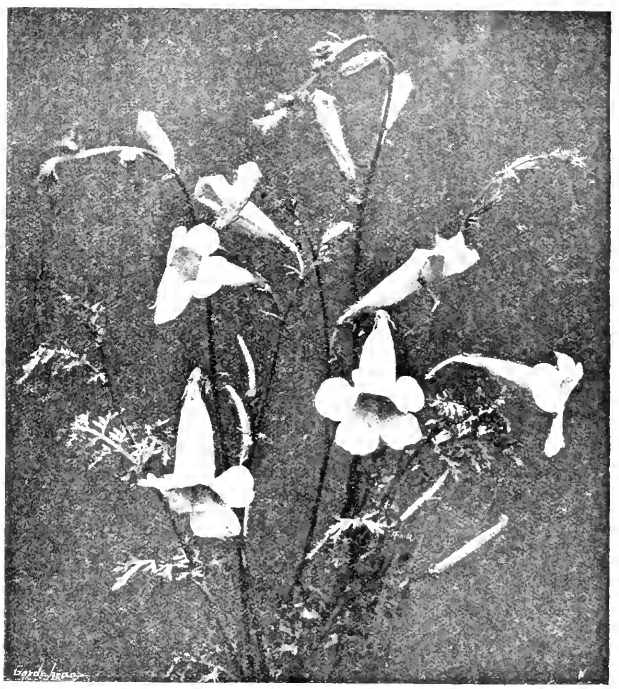

FIG. 71.—A YELLOW-FLOWERED FORM OF INCARVILLEA VARIABILIS.

hairs. There are several forms of this species, and it is apparently true that the variety, which used to be largely cultivated as the source of Saffron, has been so long increased by offsets and transplantation that it has lost the power of reproducing itself by seeds.

By far the best of all the white-flowered Crocuses at October is a species that has not long been distributed in our gardens under the name of C. marathonisius (see fig. 70). If it is indeed only a variety of C. Boryi it is a vast improvement on the type. The flowers are large and of a peculiarly solid pure white, which is set off by the golden throat and the orange-scarlet style. The leaves are sufficiently developed at flowering time to give some support to the flowers and to guard them from the reproach of looking naked that is sometimes level at the earliest flowering species. C. marathonisius, as well as the white form of C. speciosus described above, comes quite true from seed. It is a vigorous grower and certainly deserves a place in every garden.

C. Salzmannii, from the south of Spain and North Africa, is another October-flowering species, of which the leaves are quite appreciably developed before the flowers appear. It is a sturdy species, forming large corms that throw up several flowers of a good bluish-lilac shade.

All these species of Crocus are well worth growing in pots as well as in the open ground. The corms should be potted early in July or August, and the pots should then be plunged in earth or ashes until the tips of the growths burst through the surface. The flowers will then develop rapidly if the pots are stood either in a sunny window or in a cold frame, and the protection from heavy rain that they thus obtain enables the flowers to develop even more perfectly than is sometimes the case when they are grown with no protection in the open ground. W. *R. Dykes, Charterhouse, Godalming.*

NEW OR NOTEWORTHY PLANTS.

HELICHRYSUM COOPERI, HARVEY.

In 1905, the Botanical Institute at Montpellier received a parcel of plants from Basutoland from the Rev. Mr. Dieterlin. They were identified by my friend, Monsieur Daveau, the Conservateur of the Jardin des Plantes. Under the number 346, and the vernacular name of "Phoho ea Thaba," he recognised a specimen as Helichrysum Cooperi described by Harvey. Seeds were sent to me, and now, after some ten years, the plants have become sub-spontaneous in my garden, surviving even the most rigorous winters without protection. They are not, however, hardy at Montpellier, for there they have been killed by frost several times. Helichrysum Cooperi is very much less ornamental than H. bracteatum; still, its heads of brilliant yellow, forming a flat disc, measure in inch in diameter. The leaves are large, mealy, and whitish. The plant requires to be treated as a biennial. *F. Denis, Balaruc les Bains, Herault, France.*

A NEW INCARVILLEA.

The new, yellow-flowered Incarvillea illustrated in fig. 71 is abundant on the hot, bare slopes about Siku, etc., in the south-west corner of Kansu, especially frequenting steep and stony banks, and never ascending to the sub-alpine zone. Its flowering season begins in May, and is not wholly over by November, so that some of its yellow trumpets are almost always open between 6-6,500 feet. In nature it is certainly perennial. At Edinburgh it was first named Incarvillea variabilis var., though the plant is singularly stable, and never shows any trace of pink in the flowers. Seeds have germinated with great ease in the garden, and the plant grows and flowers with more freedom than I. variabilis. It remains to be seen if it will prove hardy in this country. In the *Botanical Magazine*, t. 7,651 (1899), Sir Joseph Hooker, describing I. variabilis, states that a yellow-flowered variety of it had been found in Eastern Tibet.

Professor I. Bayley Balfour, of the Royal Botanic Gardens, Edinburgh, contributes the following particulars of the plant:—"The plant was raised from seeds collected by Mr. Farrer and Mr. Purdom in very hot, dry, stony places of the loess region about Siku in Kansu, where it flowers beautifully from May to November. Incarvillea variabilis is well named, for it shows much variation, and several of the varieties have been named by Batalin. Mr. Farrer's plant was examined critically here by Mr. W. W. Smith, who found that it is very near Batalin's I. variabilis var. Przewalskii, a plant collected in Kansu by Przewalski. But it does not quite match that variety, which is hairy all over, while Mr. Farrer's plant is glabrous. We were content at first to record it as a variety of I. variabilis without precise name, but later, for the sake of distinction in gardens, Mr. W. W. Smith gave the name Incarvillea variabilis var. Farreri to Mr. Farrer's plant, and under that name we are growing it here. It has flowered freely, and has produced seed during the past two seasons."

LETTERS FROM SOLDIER-GARDENERS.

GARDENS IN THE WAR AREA.

Being temporarily stationed close by a ruined village, I took advantage of a quiet afternoon to wander over what remains of the gardens with the object of seeing to what extent plants and trees had withstood the destructive effects of war. This particular village, with its gardens and paddocks, occupies about 200 acres. It has been occupied by the enemy on two occasions and has suffered more than most places I have seen—hardly a wall remains standing. The whole area is littered with débris and punctured with shell-holes. Trenches and wire entanglements run through many of the gardens.

As may be expected, weeds are rampant. Ranunculus repens is the most widespread, and after that Mercurialis annua. The former clearly illustrates the effectiveness of vegetative reproduction.

Nettles, Docks, Sow Thistles, Plantains, and Chickweed are luxuriating. Convolvulus arvensis covers old shell-holes with a tangle of growth. Atropa Belladonna and Verbascum Thapsus are conspicuous on the heaps of débris.

Although the season is rather late (October) a number of cultivated plants are in flower. The two most common are Perennial Sunflowers and Asters (Michaelmas Daisies), which seem to thrive in the most amazing places, lending a bright touch of colour to the desolate scene. Several varieties of Phlox, Japanese Anemones, Globe Thistle, Snapdragon, French Marigold, and a pink Sedum are to be seen in flower here

and there. A single bush of Fuchsia and a few Roses complete the display.

Other plants which survive but are not in flower include Paeonies, Pinks, Sweet Williams, various Saxifragas, Iris, Montbretias, variegated Pulmonaria, Solidago, Aquilegias, Primroses and Violets.

in the timber and by atmospheric moisture. I have been surprised to find several of these cut-down trees bearing foliage, and even a few precocious flowers now, but these are specimens which have a small portion of wood about an inch in width joining the prostrate tree to the stump. A fresh growth of wood is gradually

part of the country, but has met with a similar fate. It exhibits amazing vitality—in all examples I have seen the stumps have broken into a mass of vigorous growth.

Among rarer subjects which have been senselessly hacked down I noticed a Tulip tree (Liriodendron) of 8 inches diameter, a golden Yew, and a handsome weeping Ash. *Alfred B. Meggles, 2nd Lieutenant, R.G.A.*

FIG. 72.—SUNK GARDEN AT MUCKROSS ABBEY, THE RESIDENCE OF A. R. VINCENT, ESQ.

I remember seeing a pleasing display of Primroses, Snowdrops and Crocuses in the neighbourhood last spring.

The following shrubs were noticed: Weigela, Forsythia, Tamarix, Berberis, Rhus, Rhododendron, Ceanothus, Pyracantha, Salvia, Phlomis, Euonymus, species of Spiræa, Quince, Cornus and Lilacs. A wall of the Wistaria clings to the remains of a once pretty. Most of the shrubs have been damaged by shell splinters, but not sufficiently to destroy them.

Asparagus, Spinach, Chicory, and Onions are the only representatives of vegetables left in the plots.

Currant and Gooseberry bushes are very plentiful, and with a judicious thinning later should be little the worse for their long neglect. Autumn Raspberries, both red and yellow varieties, are in fruit, but the plants are getting into a very weedy condition.

Strawberry runners have spread far and wide, rivalling even the creeping Buttercup in their riotous growth.

Every tree of any size was cut or hacked down by the enemy in 1916, and it grieves one to see such large numbers of fine trees mutilated in this abominable way.

Poplars, Elms, and other trees, which form so familiar a feature of the French roads, are often cut down on high elevations with the object of preventing them being used as observation posts, but fruit and decorative trees have been wantonly destroyed in this village.

Apple, Pear, Plum and Cherry trees, many of them with stems 1 foot or 18 inches in diameter, have been destroyed in scores, the usual method adopted being to saw them through about 2 feet above ground, though blasting was resorted to in many instances.

Many readers will remember seeing photographs in the illustrated weekly papers last year showing similar trees lying on the ground but full of blossom. The flowers, of course, were developed from buds already formed before the trees were cut down, sustained by the sap stored

MUCKROSS ABBEY.

RECENTLY I had the privilege of visiting Muckross Abbey, which, standing in a demesne of some 15,000 acres, includes part of Killarney's beautiful "lakes and fells," and was greatly interested in the various improvements that have been carried out since 1911, when the estate passed into the hands of its present owner, A. R. Vincent, Esq. Both Mr. and Mrs. Vincent are keen gardeners, and, under their supervision, the gardens are being entirely remodelled. New glasshouses have been erected by Messrs. Richardson, of Darlington, and indoor Vines, Peaches and Figs are all carrying good crops of fruit.

The kitchen garden (see fig. 73) is about 5 acres in extent, and is well stocked with good crops. Borders of the kitchen garden have been newly planted with young, healthy fruit trees, but, as in most places this year, with the exception of soft fruits, two crops were light. Herbaceous borders, also borders of Carnations, Gladioli, Roses and Sweet Peas were at the time of my visit making a grand display.

The rock garden is most interesting; it is composed of carboniferous limestone, covering about 1 acre of ground, and rising to a height of about 30 feet. At present it is only planted on the south side, and parts for paths have been blocked out and steps formed. The north side has still to be attacked, and when this is done, and the whole developed as contemplated, it will probably be the finest rock garden in Ireland. During May and June it was a mass of flower, for Saxifragas, Potentillas, Dianthuses, Lithospermums, Campanulas and Primulas, are planted in profusion, and also dwarf Conifers.

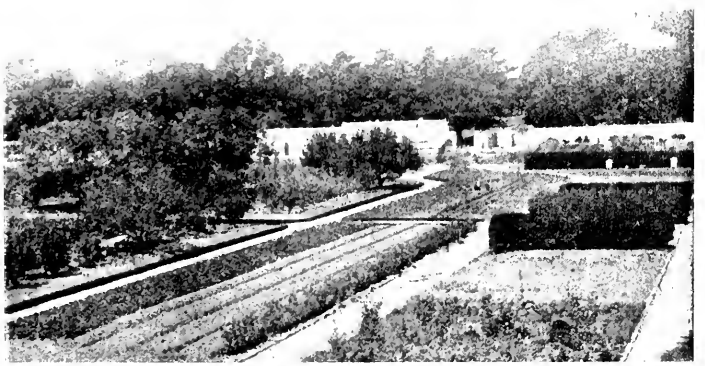

FIG. 73.—MUCKROSS ABBEY: THE KITCHEN GARDEN.

such growths, from trees which have not been cruelly cut, should be capable of producing useful fruit in a few years' time, but it will be necessary to replant most of the gardens and paddocks with young trees.

The Walnut is a very common tree in this

Unfortunately the heavy rainfall of this district renders the cultivation of certain Alpines very difficult.

A sunk garden (see fig. 72), with paved walks designed by Messrs. R. Wallace and Co., Colchester, has been formed near the mansion, and

is filled with sweetly-scented Roses, Lavender, Rosemary, Pinks, Verbena, Nicotiana, and other old-fashioned flowers. Woodlands walks have been made, and are to be greatly extended. They have been planted on either side with Liliums, Montbretias, and other perennial flowers, and when finished will add a charm to this lovely place, nestling beneath the Torc Mountain.

The gardener, Mr. C. Bennett, is to be congratulated on the excellent condition of all departments under his care. *E. S.*

THE ALPINE GARDEN.

CALCEOLARIA POLYRRHIZA.

Of the reputedly hardy Calceolarias suitable for the rock garden, the dwarf C. polyrrhiza is probably the one which is least liable to disappear. The others, e.g., C. integrifolia, C. plantaginea, and C. Kellyana are fairly hardy but are not so able to take care of themselves as the one under notice, which is of creeping habit, and needs watching if grown in the vicinity of other choice Alpines, as it may smother its neighbours. In a position where it can be allowed to ramble at will it soon spreads over a fair space, and produces an abundance of its curiously-shaped yellow flowers with brown spots; the blossoms are more helmet-shaped than those of some of its allies. The height of C. polyrrhiza is only about 6 inches. The plant likes a sunny position with me, and is allowed to ramble about and come up among some patches of Heaths, and among the stones at the base of a rockery. In some places it appears to like a boggy soil, but this is not necessary for its well-being. There are differences in the quality of some of the plants sold as C. polyrrhiza: some produce more and better flowers than the others. *S. Arnott.*

FOREIGN CORRESPONDENCE.

NEW FORMS OF RED SUNFLOWERS

The colour-patterns first described in the red Sunflowers (Helianthus annuus, varieties) were comparatively few, but this year we have quite a series hitherto unrecorded. The following are some of the more interesting or striking:—

1. Vinous series; wine-red on a pale or primrose background. Disc dark.

(a) flavobasis, n. var. Rays vinous, a little dilute apically; about basal 12 mm. bright canary yellow.

(b) trizonatus, n. var. Same as last, but vinous, strongly dilute or whitish on apical third, leaving a broad ring of deep vinous red through the middle of the rays. A very striking form.

(c) semivinosus, n. var. Rays with basal half (except yellow at extreme base) vinous; apical half pale yellow.

(d) reversus, n. var. Reverse of the last; almost basal half canary yellow; apical half rather dilute vinous.

(e) pallescens, n. var. Dilute vinous, with pallid apices, giving a curious pale flower-head.

(f) passiflora, n. var. Disc very dark, with purplish tint. Rays about 35, in two rows. Rays pale, approaching straw yellow, with basal third or less deep vinous, nearly the groat of Gravereaux, but with a little more blue in it. A very pretty form, recalling a Passion-flower in the colour-effect.

(g) apicalis, n. var. Basal two-thirds of rays rich vinous red; apical third pale primrose.

2. Chestnut series; chestnut-red on orange. Disc dark.

(h) apicalis, n. var. Same pattern as (g).

(i) basalis, n. var. Chestnut reduced to basal third or two-fifths, the rest of the ray orange.

(j) dilutus, n. var. Chestnut on basal half of ray, but so dilute as to be scarcely noticeable.

(k) latibasis, n. var. Basal half, or nearly half, of rays rich orange, the part beyond dark chestnut.

The rays also vary much in form, and a long series of types will eventually be described. The following may be noted now:—

(l) convolutus, n. var. Margins of rays curled upward (inward), especially at the beginning of the flowering period of the head. The effect is very striking in zonatus forms, with a broad ring of chestnut across middle of rays, because the upturned edges are orange, contrasting.

(m) revolutus, n. var. Margins of rays curled downward, producing a narrowing effect. This is not developed in the younger heads, but only at maturity, contrary to the condition in the last variety. It has been found in the wild form (lenticularis), as well as in our cultures.

I am accumulating data for a full account of the characters and variations in Helianthus, and shall be very grateful for any information, which will be duly credited. It is especially desirable to know of the appearance of any new varieties, either of the annual or perennial species. Drawings or photographs should be made (the latter with a colour screen), when possible. Rays should be pressed separately; they are not so good when the attempt is made to preserve the whole head. Information is also greatly desired concerning the Jerusalem Artichoke, Helianthus tuberosus, and its varieties. We are carrying on experiments with this plant in Boulder, and expect to have many interesting facts to report later. *T. D. A. Cockerell, Boulder, Colorado.*

HARDY FLOWER BORDER.

STACHYS BETONICA VAR. ALBA.

Being interested in albinos generally I was particularly pleased with the form collected by Mr. R. Irwin Lynch, and illustrated on p. 127, after having been cultivated by him. What impressed me most forcibly was the dwarf habit of the plant (5 to 7 inches when passing into fruit). The ordinary purple form is a sprightly plant, even in the wild state, and I have seen it flowering at various heights, including dwarfer ones than Mr. Lynch mentions, but considered the dwarf habit was due to the nature of the soil or a dry situation, and that all would have grown taller if planted in good garden soil. No doubt there are pigmies amongst them, but garden cultivation is necessary to prove this. The profuse-flowering nature of the variety also appealed to me. The albino of the Betony is not a common one, as I had never seen it till I collected flowering specimens of two plants within a hundred yards of one another in Berkshire in 1915, although I have been noting albinos since I was at school. There is precedent for bringing an albino of a British plant before the Floral Committee of the R.H.S., for Malva moschata alba had a First-class Certificate on August 9, 1881. This I have since collected on Salisbury Plain. The first albino I ever observed was Campanula rotundifolia var. alba. The most common wild one is Cnicus palustris var. alba, found all over Britain. Other plants frequently represented by albino forms are Calluna vulgaris, Erica Tetralix, Rosa dumetorum, Viola lutea, Galeopsis Tetrahit, Fritillaria Meleagris (local), and Viola odorata. Altogether I have a record of having gathered or observed 43 albinos of British species of plants. *John Fraser.*

The Week's Work.

THE KITCHEN GARDEN.

By F. Jordan, Gardener to Lieut.-Col. Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

French Beans.—Make sowings of French Beans every fortnight, according to requirements, placing seven or eight seeds in each 8-inch pot, which should be about three-parts filled with soil. Plants which have been grown in cool houses may be forced in a temperature of 55° or 60°, allowing them a free circulation of air in favourable weather. See that the roots are well supplied with water, and, as the Beans approach maturity, give weak applications of liquid manure, with light syringings overhead, but the latter only on bright days. Top dress later plants as they become ready, and arrange a few small twigs in each pot as supports. Take care not to over-water the roots.

Winter Tomatos.—After November it will be a more difficult task to obtain ripe fruits of Tomato than hitherto. Greater care will be needed in watering and ventilating. Light top-dressings of rich compost will benefit plants that are fruiting freely, and they should also receive an occasional watering with diluted liquid manure. Pollinate the flowers daily, maintain a moderately dry atmosphere, and let the temperature be as near 55° as possible. Do not allow the fruits to hang on the plants after they have coloured. They will keep well in a warm, dry room. Light fumigations should be given the house on every alternate night for a week or ten days if white fly is troublesome; one or two fumigations would be of no avail, and strong fumigations are harmful.

Ground Operations. — Ground intended for Onions and other deep-rooting crops should be prepared at this season. Much ground of poor quality that has recently been brought under cultivation, and where surface digging only has been practised, would be much improved by deeper cultivation. It is impossible to give advice that will meet every case, and considerable judgment must be exercised in the matter. A light, open situation should be chosen for Onions. The sooner all kinds of light soils intended for this crop are trenched the better, and it is almost impossible to apply too much manure. Farmyard manure is best, and at least 2 feet of soil should be broken up and the manure well incorporated, leaving the surface as rough as possible. With the exception of sticky clay land the bottom soil should be brought to the surface, and much may be done to improve such soils by breaking up the sub soil and incorporating with it long manure, with a liberal addition of lime rubble, burnt garden refuse, road scrapings, and prepared garden rubbish. I do not advocate burying a large quantity of rich manure in the bottom spit; as a rule it is better for most plants to grow near the surface, where the roots obtain most warmth.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Epidendrum prismatocarpum. — Plants of Epidendrum prismatocarpum are rooting freely, and any necessary re-potting should be attended to at once. Ordinary flower-pots form the best receptacles, and they should be filled one-third their depth with clean crocks for drainage. A mixture of A1 fibre or Osmunda fibre cut up rather roughly and a sprinkling of crushed crocks provides a suitable rooting medium. After the roots have grown into the compost give them plenty of water, and continue to do so until growth is complete, when only sufficient moisture is needed to prevent the roots from perishing. A slight shrivelling of the pseudo-bulbs during the resting period will do no harm, for although the plant is evergreen it seldom flowers satisfactorily unless given a decided rest for a season-

Cypripedium.—Such Cypripediums as C. bellatulum, C. concolor, C. niveum, C. Godefroyae and the many hybrids of this section, should receive very careful treatment during the winter. Having thick, fleshy leaves, the plants do not require so much water at their roots as other Cypripediums. The compost should be allowed to become quite dry between each application of water. The receptacle may be immersed to the rim, or the water poured around the outer edges of the soil, the object being to prevent moisture lodging in the axils of the leaves; care should also be taken to prevent water dripping from the roof coming in contact with the foliage. In removing the flower-scapes cut them clean to the base, for it a portion of the stalk is left it sometimes sets up decay, which soon proves fatal to the plant. The winter-flowering Cypripediums, including C. insigne, its varieties, and many hybrids, are near the flowering stage, and as the flower-scapes attain sufficient length they should be neatly tied to stakes. The plants should be kept moist at the roots, for if the leaves were allowed to shrivel at this stage it would prove very injurious to the constitution of the plant.

Masdevallia.—Plants of Masdevallia tovarensis are developing their flower-spikes, and specimens that have been grown in cool conditions during the summer should be removed to a house having an intermediate temperature. Exercise great care in watering these plants at this season; the compost should always be allowed to become dry between each application of water, as an excess of moisture at the roots may cause the foliage to damp and fall from the plants.

Coelogyne cristata.—This Orchid and its varieties are nearing the completion of the season's growth, and will soon be sending up flower-spikes from the new pseudo-bulbs, at which stage the supply of water at the roots should be reduced, but not to such an extent as to cause the plant to suffer from drought. Well-rooted, pot bound plants of this species will be greatly benefited from now onwards to the flowering stage by periodical applications of weak liquid manure made from cowdung, C. barbata, C. ocellata, and C. elata are developing flower-spikes, and should be well supplied with moisture until their flowering season is over.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Bouvardia.—Keep a sharp watch for red spider, which often attacks Bouvardias after they have been placed indoors, and should any of the insects be detected dip the plants in a strong insecticide. The plants should not be coddled if healthy flowers are required, and they should be grown near the roof glass. Part of the batch of Bouvardias may be brought into flower a little earlier than the rest by growing the plants in slight warmth, but fire-heat should never be used to excess.

Luculia gratissima.—This exotic is one of the most beautiful of cool greenhouse plants; its successful culture depends almost entirely on a suitable glasshouse in which to grow it. A house which can be well ventilated all through the growing season is absolutely essential. The roots should be planted in a restricted, well-drained border. The plants usually pass out of flower about the end of November, and if they have filled their allotted space the flowering wood may be shortened severely. During the winter the plants should be rested, keeping the roots on the dry side, and the house as cool as possible. Bouvardias should not, however, be exposed to severe frost.

Violets.—Let Violets growing in frames have an abundance of fresh air at all times; when the weather is favourable, remove the lights entirely, and do not close the frame except when severe frost is imminent. Water the roots thoroughly when they are in need of moisture, and do this on a fine, bright morning to allow the foliage to become dry before nightfall. Examine the plants about once a week, and remove decayed foliage. Keep a sharp watch for slugs.

Bulbs in Pots.—Recently potted bulbs need careful attention, as rats and mice often damage them. When the foliage has made an inch or two of growth the plants should be placed in a cold frame to which plenty of air is admitted during favourable weather. Do not allow the roots to suffer for want of moisture. Place early-flowering Narcissi and Roman Hyacinths in gentle warmth as occasion demands. Bulbs of Lilium candidum which were potted early in the season may also be placed in a warm house.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

Humea elegans.—This handsome plant is frequently difficult to winter, sometimes dying or at least losing many of its lower leaves. A low temperature, free from frost and damp, suits it best, and without letting the soil in the pots become very dry for the next eight or nine weeks, be very careful in applying water. By the end of January, if these conditions are observed, the plants should be ready for potting, finally, after which fresh growth will be renewed with vigour, and handsome specimens obtained for planting in beds or standing in pots out of doors during the summer.

Surface Dressing. It is of great benefit to bedded-out Pinetums, after removing decayed foliage, to surface-dress the plants. Nothing seems to suit them so well as cow manure laid over the roots from which the soil has been withdrawn, to be returned after the dressing has been applied. Spanish and English Irises, and indeed all bulbous Irises appreciate a rich surface dressing but no growth commences. If it is laid a 2-inch thick layer of compost, which may consist of soot, potted manure, old potting soil, and material from Mushroom beds, should be laid evenly over the surface. The ground, it is perhaps needless to say, should be perfectly cleaned of rubbish before the compost is applied. Material of the same nature may also be applied to Hellebores, Christmas Roses, and Lily of the Valley.

Carnations. It is a good plan to examine beds of Carnations before the winter to stir the soil and scatter soot around the plants. So that the wind is not harming the plants by twisting them round. If the soil is not very light to-day it may be an advantage to make it firm by means of foot pressure. Carnations being scattered in pots should be kept in a cool position so that they need no water at the roots until January. Some dry, fallen Beech leaves scattered among the plants will serve to prevent frost breaking the pots. Even in very cold weather air should be admitted freely to the frames in which Carnations are grown, and every opportunity taken of fine weather to remove the lights altogether. Usually root cuttings of these plants are in the season in a hot frame; such plants are valuable for late flowering, and are ready for transference to pots at about this time, and should be kept dormant until renewed growth starts them into new growth.

FRUITS UNDER GLASS.

By W. J. GRISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

Early Vines. The earliest permanent vines should be pruned finally directly the foliage has fallen. Old vines which have been forced for a number of years should not be pruned too severely unless the back buds are well developed and prominent, when close pruning is advisable. The glass and woodwork should be well cleansed with strong soapy water, and the walls washed with fresh lime. Half a pound of Gishurst Compound to two gallons of very warm water will make a suitable wash for the main stems, which should not be scraped, but loose bark that comes off freely may be removed. Where mealy bug is troublesome more bark may be removed and the rods dressed with a mixture of tar and dry soil. Half a pint of tar to a gallon of dry soil, mixed to the consistency of paint, is a safe specific, but it must not come into contact with the buds. Keep the house well ventilated until the time for forcing arrives.

Pot Vines.—Much the best results will be obtained by deferring the forcing of pot vines until the new year. In the meantime, the canes should be shortened to a suitable length, divested of all laterals, and the cut surfaces painted with styptic should they exhibit any signs of bleeding. After they have been washed in strong soapy water, carefully tie the canes in a circle to two stakes inserted in the pots. Top-dress the roots with rich, fibrous loam mixed with a little bone-meal. The pots should be plunged to their rims in bracken Fern, tree leaves, or ashes, in a cold house, to protect them from frost.

Cucumbers.—Direct syringing of Cucumber plants intended for winter fruiting should be discontinued, and atmospheric moisture maintained by slightly damping the paths and keeping the evaporating troughs full of diluted liquid manure or clear water. Keep the roof glass and floors scrupulously clean and coat the walls with fresh limewash. As the roots appear through the surface of the soil cover them with light top-dressings composed of loam, old lime rubble, a little charcoal or wood ash; give them an occasional sprinkling of a concentrated manure. Water should be given less frequently, but in sufficient quantity to reach the roots, and should always be used tepid. For the next two months or more the plants will not make much progress, but if the laterals are allowed plenty of space, and only a few fruits permitted to develop, the plants will grow freely at the turn of the year. The fruits should be cut before they attain to full size, and when cut may be kept for a long time with their stalk ends placed in bowls of water. To maintain the necessary night temperature, which should range between 60° and 65°, requires fuel, and I think prospective growers would be well advised to discard their plants, and reserve their fuel supply for the turn of the year.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Autumn-fruiting Raspberries.—We are still gathering berries of autumn fruiting Raspberries daily for dessert, and in the best possible condition. Having a surplus over and above our daily requirements, some have been used for preserving and also for stewing. These Raspberries have proved a great success this season; I do not think we have ever had them in better condition. The plants resist damp better than the summer varieties. On the Continent, and more particularly in France, these autumn Raspberries are more prized than in this country. By covering the rows with glass early in October the supply will be considerably prolonged. Such an arrangement could easily be devised somewhat after the method adopted to protect Chrysanthemums. Our small fruit gardens are netted, and the netting protects the Raspberries somewhat, but early autumn fogs, which cause the leaves to drop prematurely, and spoil the quality of the berries, do more harm than cold.

Planting Fruit Trees. The weather of October was favourable for operations in fruit tree nurseries, but the nurserymen are handicapped by a shortage of labour, therefore those who are expecting their newly ordered trees must exercise patience. Have everything in readiness when they arrive, so that there may be no delay in planting. Delay in railway transit may occur under present conditions, and the state of the roots should be ascertained when unpacking the trees, for it may be necessary to give the roots a soaking in water before they are planted. The weather is suitable for planting operations, and an effort should be made to concentrate on this important work whilst conditions are favourable. It should be a good season for shifting all young fruit trees; it is not desirable to have the wood over-ripened, but rather to have a plentiful supply of active sap still in the trees. In planting be careful to spread out the roots in every instance; see that none is cramped or crippled in the process of planting. Some amount of root action will soon take place, and this is all important. Make the soil firm, and wherever needed stake the trees directly they are planted. Should any part of the stems be bruised or the bark broken in transit, smear a little tar lightly over the wounds, as this may prevent canker following. Label the trees with permanent labels, and in extensive planting make a list of the trees in a book.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 45.5°.

ACTUAL TEMPERATURE:—*Gardeners' Chronicle* Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, November 6, 10 a.m.: Bar. 30.2, temp. 49°. Weather—Dull

The Ormskirk Potato Trials, 1918.

Wart disease of Potatos is spreading with disconcerting speed, and the trials conducted at Ormskirk by Mr. John Snell, and those working with him, for the Board of Agriculture are of incalculable value to all Potato growers. Whether in the garden or in the field, we are, or soon will be, face to face with the certainty that our Factors and King Edwards, our Arran Chiefs and Evergoods, our Epicures and Early Puritans will be, at lifting time, but a mass of warts, useless as food for man or beast, a menace to the health of all other Potato patches, and a dead loss to the grower. What can take their places? This pertinent question the trials conducted at Ormskirk have helped to answer. Three hundred and one stocks of Potatos were this year included in the trials carried out to determine the resistance to Wart Disease. One hundred and thirty-one of these stocks were planted for demonstration purposes, and there were one hundred and forty-seven (some of them in duplicate) sent in as new varieties for trial. In the issue for August 10, page 60, we dealt with the inspections arranged in the summer, and now that the crops have been lifted, the Food Production Department, in conjunction with the Lancashire Farmers' Association, arranged on Wednesday and Thursday, the 30th and 31st ult., an Exhibition and Conference upon the results. On the Thursday Mr. Snell informed those present at the Conference (at which, as at the Exhibition opened by Lord Bledisloe on the Wednesday, there was a good attendance) that of the new varieties in the trials only twenty-nine had proved immune. It is understood that a full report of the trials will soon be available, therefore it is unnecessary for us to refer at length to the behaviour of the varieties; but as really early immune varieties, new and old, are few, the names of those so far proved resistant may be given. They are: A1, Witchhill, Crown Jewel, Sutton's Ashleaf, America, Coronation, Resistant Snowdrop, Dargill Early, and Arran Rose. Some of these varieties are of low-cropping capacity. Edzell Blue is often included in the list, but only because it may be lifted early, not because this variety finishes early. Of some of these sorts the stocks are small, and both here and among other types of Potato there is ample scope for plant-breeders.

Apart from one other important matter, to which we refer below, the principal interest of the Conference centred around two questions: the possibility of raising again types so similar to already existing varieties as to be indistinguishable from them; and the origin of new varieties by bud-sports or as graft-hybrids. The latter question has already been debated in our columns, and Mr. Arthur W. Sutton read an interesting review of the present state of our knowledge of the matter, concluding that the only authentic examples of such origin are a few colour-forms, and commenting upon the unreliability of the evidence adduced as proof of the contrary. In view of the interest taken in the subject, we have published the principal details given in Mr Sutton's paper on page 190.

While we cannot accept as proven the impossibility of bud-sporting occurring so as to produce new varieties, it is clear that the occurrence is at least very rare, and that as immunity to Wart Disease is a varietal characteristic, there is every reason to believe that it will be a persistent character, and that the basis of the trials now being carried out is thoroughly sound. There seems no good ground for accepting evidence that the alleged newly-developed form is identical with an old one in all discernible characters as conclusive proof that the form has not been newly developed, whether as a bud-sport or as a seedling. It would, in fact, be strange if the same combination of characters should not arise more than once when multitudes of seedlings are raised, and this not only when the original parental forms are being used, but also even when other forms are being experimented with. We discerned a tendency to regard such evidence as valid at the Conference, but, taken alone, we cannot accept it as conclusive.

Among a batch of selfed seedlings of, say, Factor, one or two may well possess the characters of their parent in such a degree as to be indistinguishable from it, though the majority may be dissimilar from it and from one another. The point cannot be settled by discussion, but only by careful experiment carried out over a lengthy period. Mr. John Snell pointed out that of the 113 forms in the trial 20 were similar to Up to Date in habit and susceptibility to Wart Disease, and among them some were said to be seedlings. So with other supposed new forms. Ten were like British Queen, eleven seedlings of, or selections from, President, seven like Northern Star, three like Sharpe's Express, and one each like Duke of York and Epicure, and in every case they, like their prototypes, proved susceptible. It seems, therefore, if these be seedlings, the use of susceptible varieties as seed parents cannot be expected, at least in the first generation, to give immune ones.

There is abundant work still awaiting the doing, and all will be glad to hear that there is good prospect of the speedy establishment of a branch of the National Institute of Agricultural Botany at Ormskirk to deal with these and related problems. Mr. Lawrence Weaver, who took the chair at the Conference, gave an account of the progress made towards the aims of the Institute, and announced the probability that a farm of 56½ acres would soon be acquired for the Potato work at Ormskirk.

The show itself embraced a large number of exhibits of Potatos of commercial value, groups from some of the leading seedsmen, and various classes, such as for the largest individual Potato. The largest group was one showing the varieties grown in the Board's trials, and nothing could be more impressive as to the dire effects of the Wart Disease than the long range of plates of many varieties all attacked by it; and nothing more promising for future success than the smaller number of clean tubers, including such new varieties as Majestic, Arran Rose, The Bishop (if it prove distinct), Arran Comrade, and America, and the better known Great Scot, Kerr's Pink, Lochar, Abundance, and White City. Two or three sorts are, for one reason or another, still classed as doubtfully resistant, and they will need to be tried another season.

In his interesting remarks at the Conference Mr. Snell pointed out some of the difficulties experienced in carrying out the trials, and incidentally the difficulties existing in securing true stocks. Several forms masquerading under the same well-known name, many names for the same type, guesses as to origins, mixing of stocks (sometimes easy, sometimes difficult to detect), and the like, all help to confuse the public and retard progress in suppressing such a trouble as the Wart Disease. They cannot all be rectified in one set of trials, but the prospect of an Institute devoted to these problems, so long as they are approached in a spirit of honest questioning and with scientific imagination, leads us to hope for much progress in the future.

Queen Mary and Food Production.—The Royal Horticultural Society's Food Production Exhibit, staged at the Exhibition of the Women's Institutes held at the Caxton Hall, Westminster, from October 25 to 28, was inspected by her Majesty the QUEEN, who was accompanied by the Princess MARY. Her Majesty and her Royal Highness showed great interest in the various models and specimens staged, and at the close of their inspection expressed their keen appreciation of the work the Society was doing, and wished it every success in its work of furthering increased food production in orchards, gardens, and allotments throughout the country. The Society's exhibit has this year been sent to no fewer than twenty-six important towns and centres in England, and in all cases it has been influential in extending a knowledge of garden work. Applications for this display will be welcomed from centres

where Food Production Exhibitions are being organised. The whole exhibit occupies a space about 80 feet long by 6 feet wide, and is sent free of cost, with an expert representative who remains in attendance.

Potato Executive Officer for Scotland.—Mr. BENJAMIN MAIN, Sub-Commissioner of the Agricultural Section, National Service Department, Perth, has been appointed Potato Executive Officer for Scotland. His address is 20, Grosvenor Street, Edinburgh.

Award of the Robert White Medal.—The Committee of the Massachusetts Horticultural Society, as trustees for the Robert White Memorial Fund, has selected Dr. VAN FLEET as the recipient of the Robert White Medal for 1918. Dr. VAN FLEET stands in the forefront of hybridisers and his productions include American Pillar and numerous other Roses, Strawberries, Gladioli, Tomatos, a Canna, a Sugar Corn, and a new Gooseberry. He was trained as a surgeon, but now devotes most of his time to experimental horticulture in his garden at Little Silver, New Jersey, U.S.A. At present Dr. VAN FLEET is endeavouring to raise disease resistant Chestnuts, as well as disease-resistant forms of orchard fruits and small fruits and in this work he is utilising the new species introduced into America through the Arnold Arboretum and the Federal Office of Foreign Seed and Plant Introduction.

The Liberation of Bruges.—The recent successes in Belgium have resulted in the liberation of the town of Bruges from the enemy. It is interesting to learn that business at Messrs. SANDERS' nursery establishment at St. Andre, Bruges, has been carried on by the staff during the four years the town has been in the occupation of the Germans. Messrs. SANDERS have received a letter from the manager, Mr. I. MELLSTROM, informing them that he is well, but that the nursery has suffered considerable damage, mainly in broken glass. He also states that they have been able to maintain a portion of the stock of plants. It is regrettable that the head of the clerical department was killed on the day before the town was liberated. During the earlier part of the war business was possible, mainly with America, but in recent times all communication with the head establishment at St. Albans has ceased and there was no knowledge as to whether the nursery was even in existence. It is to be hoped that the many large nursery establishments in and about Ghent may be equally fortunate in escaping total destruction, as the nursery trade of Ghent and Bruges was one of the principal industries of this part of Belgium.

Laelio-Cattleya Linda.—An Award of Merit was obtained by Messrs. J. and A. MCBEAN, Cooksbridge, at the meeting of the Orchid Committee of the Royal Horticultural Society on October 22 for this pretty hybrid (see fig. 74). It was obtained as a cross between C. Dowiana aurea and L.-C. Arachnites (labiata × L.-C. Haroldiana), and is a useful addition to this section of autumn flowering Orchids. The form and fine substance of the flower follow the large flowered Cattleyas used in its production, the unusual tints of its sepals and petals being chiefly derived from L.-C. Haroldiana, one of the parents of L.-C. Arachnites. The sepals and petals are light rose-mauve, with a slight gold shade; the lip is a common mauve-purple with yellow disc, and has broad lines. The flowers are fragrant, and have good lasting qualities which make them suitable for decorative purposes.

A British Tribute to Fallen French Comrades. The wreath illustrated in fig. 75 has been forwarded by the "Comrades of the Great War" to be laid in the Pantheon, Paris, on All Souls' Day. Numbers of the graves of our heroes who have laid down their lives on the fields of France have been carefully tended by the people of France, and the token was the outcome of a desire to render grateful homage and thanks from Great Britain for this sympathetic care and attention. The Hon. VICARY GIBBS undertook to have the wreath prepared in the gardens of Aldenham House, and it was conveyed to France on October 31, bearing the following inscription: "To the glorious memory of our French Comrades who have given their lives for France and the cause of the Allies. From the British Comrades of the Great War. All Souls' Day, 1918."

War Item. Pte. ROBERT BARTOOT, only child of Mr. and Mrs. BARTOOT, Mayfield Gardens, Woolston, Southampton, has been killed in France. While employed at Battalion Headquarters as a runner he was sent back to the transport lines with a message on the night of October 10; he delivered the message, but did not return. His body has since been found, and it appears he was killed by a piece of shell. The many friends of Mr. and Mrs. BARTOOT

FIG. 74.—LAELIO-CATTLEYA LINDA.

will learn with regret of their irreparable loss. Before joining the Army Pte. BARTOOT was inside foreman at Aston Clinton Gardens.

Chamber of Horticulture. A conference of presidents and secretaries of Horticultural Trade Associations will be held at Donington House, Norfolk Street, Strand, on Tuesday, the 12th inst., at 2 p.m. Any society desiring to be represented, and not having received a formal invitation, is invited to write to the secretary, Mr. R. WYNNE, Norfolk House, Norfolk Street, Strand, intimating an intention to be present and asking for particulars.

BUD VARIATION IN POTATOS.*

THE subject of this paper has been selected in consequence partly of a recent correspondence in the horticultural press, in which one or more writers have claimed to possess new and distinct varieties of Potatos which were supposed to have arisen by bud-variation. But it was Mr Cuthbertson who first replied (see *Gard. Chron.*, Sept. 7, 1918, p. 102), and replied most effectively, to the claims made. I merely endorsing what he had said and adding further notes from my own experience.

Claims sometimes put forward seem at first sight to have such apparent foundation in fact that an examination of the possibilities for the appearance of new and distinct varieties from bud-variation may be of some interest and value.

In the first place, we need to be very exact in regard to the terms used and the meaning we attach to them, not forgetting that to others the terms may, from habit or custom, convey something different meanings.

This will be seen in the use of the word "varieties." What do we actually mean by varieties of Potatos? For all practical purposes and to all practical growers—a variety is a Potato which is as distinct from all others in regard to its identity as any one child may be when the parents are the happy progenitors of a dozen or more children. In such a family there may be, and there often is, far more family resemblance between the children than can be discovered between seedling Potatos raised from one Potato "apple" or berry, even when this is the result of self-fertilisation and not of any cross between two distinct parental forms.

If we accept "new and distinct varieties of Potatos" to mean distinct varieties, or sorts in the sense above defined, then no one here, probably, will for a moment imagine that there is any but an absolutely negative reply that can be given to the question we are considering. To apply any other meaning to the term varieties is a waste of time.

But that what might more correctly be termed "variations"—rather than varieties do occur by bud-variation is a fact we are all intimately acquainted with. The variety, i.e., the individual Potato plant, remains identically the same, but by processes of which Nature to a great extent keeps the secret, some external modifications are produced, but even then there is no duly attested instance in which such modification has affected anything more than the colour of the skin of the tubers. I know that this is the point upon which the whole question turns, but I have no hesitation whatever in repeating that no other kind of variation has ever been recorded where the claims made rest upon duly attested evidence.

In the case of Potatos, the change of colour may be either an addition of more colour as occasionally in the human subject—or a loss of colour, but generally the latter. The following are among the instances best known to us all:—

BEAUTY OF HEBRON.—This variety gave a variation by loss of the pink colour of the skin, and we then had the well-known White Beauty of Hebron, identical in every character with the original form except in colour of the tuber. It was still Beauty of Hebron, it could never be anything else, although it might seem advantageous, for reasons we need not inquire into, to attach another name to it.

FORTYFOLD.—This old favourite, with its purple and white skin, also gave rise to a white form, known as White Fortyfold.

RECTOR OF WOODSTOCK.—This variety is probably almost or quite out of cultivation now. It was a white, round Potato, raised by the late Mr. Robert Fenn, and introduced by me some 42 years ago. It gave rise to a mottled form, known for distinction as "Harlequin," but the "variation" was still the same variety, and nothing more or less.

KING EDWARD.—This more recently introduced Potato occasionally gives tubers where the pink colour extends all over the surface and not only in parts, and there are other instances which will occur to most of us.

(To be continued.)

* "Do Potatos Give Rise to New and Distinct Varieties by Bud Variation?" Paper read by Mr. Arthur W. Sutton, J.P., at the Ormskirk Potato Conference, October 31, 1918.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

The Late Mr. E. J. Allard.—All who knew the late Mr. Allard join in sorrow for his loss. I was sure that Professor Bateson would write the sympathetic notice of last week's issue, but nevertheless I have felt some responsibility, for Mr. Allard was essentially a Cambridge man. It is little, however, that I can do beyond saying that I join heartily in all the praise and appreciation of his personality and merit, already so well expressed by Professor Bateson. Mr. Allard was a valuable man to me. He came to Cambridge from Messrs. Sander and Co., St Albans, in 1895, when about 19 years of age, to fill a post in the plant-houses. He remained, doing credit to himself and gaining experience, for all but three years; he then went to Kew, returning to me, after about fifteen months, as foreman of the plant-houses. He held this position for six years and was then transferred by his own desire to be foreman of the outdoor department, a change the possibility of which stands much to his credit for capacity, range of interest and observation, because it is usual only for a foreman to continue in the charge for which his previous experience has chiefly fitted him. He was now senior foreman, and he remained, doing good work, for five years, being then chosen by Professor Bateson for the important position of superintendent at Merton that he has filled with so much credit. He spent about fourteen years at Cambridge, and was foreman for eleven years of that time. Among Mr. Allard's special interests I may mention photography. Almost all the plates in my *Book of the Iris* were from his photographs, and numerous photographs of Cambridge plants appeared in the gardening papers with his articles. For a considerable time he had charge of the meteorological readings, and his records were regarded as highly satisfactory. Mr. Allard was very popular here, and I may say for all his contemporaries that no loss could be more regretted. *R. Irwin Lynch.*

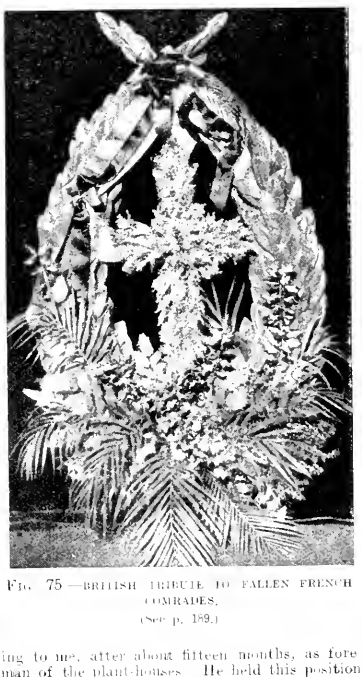

FIG. 75.—BRITISH TRIBUTE TO FALLEN FRENCH COMRADES.

(See p. 189.)

The Late Mr. J. Gardner.—It was with the deepest regret that I learned the sad news of the demise of this exceptionally promising young gardener, who I looked upon, from the time I first knew him, as one of the most likely men to reach the top rank of the profession. When my friend, Mr. Owen Thomas, first approached me as to Gardner joining the staff at Aldenham House Gardens I was somewhat sceptical as to his suitability for a gardener, having in view the very different occupation he was then following, but being assured by Mr. Owen Thomas that he was fully bent on following the same occupation as his respected father, I decided to give him the opportunity. From the first he showed evidence of great ability. Commencing, as all young gardeners should, at the bottom of the ladder, he never showed the slightest signs of shirking the roughest of the work, not once looking back with regret to his previous sedentary occupation, and quickly attained remarkable proficiency. Well educated, and of smart appearance, taking the keenest interest in everything he did, nothing being too much trouble to overcome a difficulty, and leading a clean, upright life, I can call to mind very few young men possessing so great a promise of a brilliant future, and my views were fully endorsed by the rapid strides he made. Young Gardner has laid down his life in a noble cause, and to his aged parents and young widow and family I tender my deepest sympathy. *Edwin Beckett.*

SOCIETIES.

ROYAL HORTICULTURAL.

NOVEMBER 5.—Had it not been for the exhibits provided by the National Chrysanthemum Society the London Scottish Drill Hall would have presented a very bare appearance on this date, as there were few other exhibits. The meeting was fairly well attended.

The Floral Committee granted one Award of Merit and five medals; the Fruit and Vegetable Committee had nothing whatever to do; the Orchid Committee awarded two First-class Certificates and one Award of Merit to novelties.

Floral Committee.

Present: Messrs. H. B. May (in the chair), W. J. Bean, John Green, G. Reuthe, G. Harrow, John Heal, C. R. Fielder, Chas. E. Pearson, Chas. Dixon, John Dickson, E. F. Hazelden, W. P. Thomson, Jas. Hudson, George Paul, E. H. Jenkins, J. M. McLeod, J. W. Moorman, E. A. Bowles, Sydney Morris and H. Cowley.

Two good displays of Chrysanthemums brightened up the hall. The larger one, from Mr. H. J. JONES, was a most artistic contribution, with a backing of sheaves of large blooms of Bob Pulling, Alec. Hervey, the deep crimson Mr. D. Lloyd George, and the pretty yellow incurved named Mr. F. W. Ladds. The other exhibit, from Messrs. W. WELLS AND CO., included fine examples of Princess Mary, Queen Mary, Crantordia and Bernard Goggs, the last a yellow incurved variety. In both these groups autumn foliage was pleasingly associated with the flowers.

Mr. F. H. CHAPMAN staged seedling Nerines: an unnamed variety with slatey-blue shading proved most distinct and suggested many possibilities in future colour variation. Mr. J. J. KETTLE again showed Violets in splendid form, and delightfully fragrant.

AWARD OF MERIT.

Chrysanthemum Elsie E. Gabriel.—An effective single variety of large size but with a stem that is rather slender just beneath the bloom. The colour is deep and rich old rose, with a very narrow, pale-yellowish zone around the disc. Shown by Mr. C. B. GABRIEL, Coxhill House, Chobham.

MEDALS.

Silver-gilt Flora.—To Mr. H. J. JONES, for Chrysanthemums.

Silver Flora.—To Messrs. H. B. MAY AND SONS, for Ferns and winter flowering Begonias.

Silver Banksian.—To Messrs. W. WELLS AND CO., for Chrysanthemums.

Bronze Banksian.—To Mr. J. J. KETTLE, for Violets, and to Mr. G. REUTHE, for Nerines and hardy flowers.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), William Bolton, R. Brooman-White, C. J. Lucas, J. E. Shill, W. J. Kaye, J. Charlesworth, W. H. Hatcher, Fred. Sander, E. R. Ashton, R. A. Rolfe, Pantia Ralli, Richard G. Thwaites, J. Wilson Potter, Stuart Low, and Frederick J. Hanbury.

AWARDS.

FIRST-CLASS CERTIFICATES.

Brasso-Laelio-Cattleya Antoinette Gatton Park variety (*C. Portia coerulea* × *B.-L. Helen*), from SIR JEREMIAH COLMAN, Bart., Gatton Park, Surrey (gr. Mr. J. Collier).—An interesting and charming flower of model proportions, C. Portia dominating in colour and giving improved shape, the rather angular form of the Brasso-Laelia parent being quite suppressed, the only evidence of it being in the fimbriated margin of the lip. The sepals and broad petals are bright rosy-mauve; the lip is reddish-purple, darker in the centre; the disc is yellow with gold lines from the base.

Odontoglossum Lady Veitch Hylandianum × *Armstrongiæ*, from Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells.—A magnificent flower, exceeding any Odontoglossum previously shown in size, form, and rich colouring. The two parents are "stud" varieties returned by Messrs. Armstrong and Brown. O. Hylandianum having as one of the ancestors a grand form of O. Wilckeanum. The flowers of the novelty have a clear white ground, the inner two-thirds coloured deep carmine purple, the bright dark tint passing through the substance of the segments from front to back. A few irregular white markings appear on the surface, and the lip, which is white in front, has a violet-purple blotch before the yellow crest. The flowers are 4½ inches across; the petals are 1¾ inch and the sepals 1¾ inch in width.

AWARD OF MERIT.

Cattleya Eleanore (*Bowringeana* × *T. M. Roy-croft* × *Hardyana*), shown by Mr. J. E. SHILL. The Ivy Gardens, Englefield Green. The sepals and petals are pure white. The flaring front lip of *C. Hardyana* form and is bright purple in front; the entire is light yellow and the base veined with purplish rose colour.

GROUPS.

SIR JEREMIAH COLMAN, Bart. (gr. Mr. J. Collier), arranged an interesting selection of flowers of hybrid Orchids raised at Gatton Park, and in some of which the Gatton blue-tinted forms of the species have been used as one of the parents, usually with the result that the soft blue shade has passed to the progeny. A fine example was Cattleya Portia coerulea, with a compact, bifloriferous spike of eleven flowers.

A. ASSALDO, Esq., Roschank, Mumbles, showed a selection of cut spikes of hybrids and species flowering in his gardens, including Vanda coerulea, of rich colour, taken from plants grown for years in an unheated house which receives some warmth from an opening in a heated structure adjoining. The temperature of the house in winter is said to be as low as 45° to 50°.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a group of hybrid Odontoglossums, Miltonias and Odontiodas. Novelties included Odontioda Gwendoline (Odm. eximium × Oda. Madeleine), the well-formed flower has a cream white base broadly edged with rosy lilac with dense spotting of reddish purple on the inner parts of the segments, and a rosy lilac coloured lip with a chestnut blotch; and Oda. Joyce (Odm. Harryanum × Oda. Royal Gem), cream white with dark claret markings.

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, were awarded a Silver Banksian Medal for a neat group of rare hybrids, the centre of attraction being Odontoglossum Lady Veitch. Especially noticeable was the new Brasso-Laelio-Cattleya Vuylstekeæ (C. Warscewiczii × B.-L. D. glyano-purpurata), having a finely formed flower of a delicate pink with a decided violet shade which is darkest in the centre of the lip; the disc is clear yellow.

Messrs. SANDER, St. Albans, showed six plants of their fine strain of white-petalled Cattleya Fabia alba, each with a spike of four flowers. The handsome lips varied in tints of purplish-crimson and in the shade of yellow and orange at the base.

Dr. MIGUEL LACROZE, Brymbir, Rochampton, showed Brasso-Cattleya Griselda Brymbir variety (B.-C. Mrs. J. Leemann × C. Lord Rothschild), a good form with cream-white sepals and petals and large, fine, rose-coloured lip with a dye-like disc.

Mr. J. E. SHILL showed Cypripedium Etna The Dell variety (Lecanum Chikaberryanum × Dreadnought), a massive flower of good shape.

J. ASSALDO, Esq., showed Sophro-Cattleya Faboris Assaldo's variety (C. Fabia × S. C. Doris), having a yellow ground and tinged with flaked with reddish-rose.

Fruit and Vegetable Committee.

Present: Messrs. Joseph Cheal (in the chair), Owen Thomas, J. W. Bates, W. Humphreys, A. Bullock, Frank R. Ridley, A. R. Allan, P. A. Tucker, E. A. Bunyard, W. Pope, W. H. Divers, W. Poupart, F. Jordan and Rev. W. Wilks.

NATIONAL CHRYSANTHEMUM.

NOVEMBER 5–6.—The annual show of this Society, which was held in conjunction with the R.H.S. meeting in the Drill Hall, Westminster, was even better than the most sanguine enthusiast anticipated. Most of the classes were well filled with excellent blooms, and competition generally was very keen. The show was formally opened by the President, Sir Albert Rollit, at 12.30 p.m., who announced that the Japanese Ambassador, his Excellency Viscount Chinda, had become a patron of the Society and had written expressing the great disappointment experienced by her Excellency, the Viscountess Chinda and himself that pressure of other engagements prevented them attending.

The trade displays by the RAYDON NURSERY Co. and Messrs. W. WELLS AND Co. contributed largely to the success of the show, and both occupied vases of Silver-gilt Medals of the Society.

FIRST-CLASS CERTIFICATE.

Lavender Queen.—This is a capital medium-sized Japanese variety of excellent form and substance. The colour is a clear deep mauve with a suggestion of orange-yellow at the base. The foliage is ovate-pointed. All-round this should prove a useful market variety.—Shown by Mr. NORMAN DAVIS.

COMPETITIVE CLASSES.

There were only two entries each for competition amongst affiliated societies, but the Challenge Cup and Ist Prize was awarded to the FINCHLEY CHRYSANTHEMUM SOCIETY, secretary Mr. A. Ewbank, Oak Cottage, East Finchley, for a very creditable display of vases of representative types. Of the Japanese varieties Mrs. R. C. Pulling, Wm. Vert, Capt. Fox, and Exam. were particularly good, whilst Mrs. Percy Walsh and Madame Ferlet were equally good Incurved sorts. Jessica and Mary Richardson, singles; Dorothy, Anemone-flowered, and Mme. E. Roudellan, Pompons, were also highly creditable.

The class for 36 Japanese blooms was not contested, but there were three exhibits in the class for 24 Japanese blooms, and these were particularly good. The 1st Prize collection, exhibited by Madame Thuenon (gr. Mr. A. Smith), Convent Gardens, Roehampton Lane, would have won honours at any previous show. The blooms were so large as to tax the accommodation of the regulation board, and there was no suspicion of coarseness. Yellows predominated, and of these F. S. Vallis, Primrose, Mrs. W. Rigby and Lady Talbot were very fine. Amongst the whites Queen Mary and Mrs. G. Drabble merited mention, as also did the light chestnut-coloured Rose Pocket and H. E. Converse, while the crimson W. Vert and His Majesty possessed equal depth and breadth combined with glowing colour; 2nd, Mrs. Chalmers (gr. Mr. A. B. Huddy), Farrants, Bickley, Kent, who put up fine blooms of Mrs. A. Gibson, Mrs. C. Edwards, Mr. R. Lufford and Mr. R. C. Pulling, though the latter's blooms were a trifle uneven; 3rd, Mrs. H. Fellows (gr. Mr. A. J. Smith), Tinsley House, Worplesdon.

No fewer than seven competitors were represented in the class for 12 Japanese blooms, and the chief honour was won by W. H. ALLEN, Esq. (gr. Mr. H. Blakeway), Bromham House, Bedford, with an excellent display. His blooms of Queen Mary, W. Rigby, Charlotte E. Soer and Mrs. Algernon Davis were splendid; 2nd, Mr. H. WOOLMAN, Sandy Hill Nursery, Shirley, Birmingham, whose blooms of Shirley Golden, Mrs. Algernon Davis and Mrs. Lloyd George were particularly good; 3rd, Mr. J. S. KELLY, Crescent Gardens, Esher.

Half-a-dozen good exhibits were forthcoming in the class for 6 Japanese blooms. Capt. C. O. LIDDELL (gr. Mr. E. Jones), Shirenewton Hall, Chepstow, won 1st Prize, showing splendid blooms of such as Thorpe's Beauty, Mrs. G. Drabble and Mrs. E. A. Tickle; 2nd, Mr. J. S. KELLY; 3rd, W. H. ALLEN, Esq., who was 1st with 3 magnificent blooms of Mrs. G. Drabble in the class for 3 blooms, in a vase of any white Japanese variety; 2nd, Madame Thunder. Mr. ALLEN, with equally fine blooms of Mrs. R. C. Pulling, was also 1st for a vase of 3 yellow Japanese blooms; 2nd, Mrs. FELLOWS.

The Holmes Memorial Challenge Cup was won by Mrs. Chalmers with 24 especially good Incurved blooms. Such old favourites as Buttercup, Godfrey's Eclipse, Pantia Ralli, J. W. Wynne and Mrs. J. P. Bryce were very well shown; 2nd, H. BENNETT, Esq. (gr. Mr. G. Dovel, Abbeyfield, Bickley, whose best blooms were of Mrs. T. Hartmann and Ethel Thorp. Mrs. CHALMERS also won 1st Prizes with splendid flowers in the classes for 12 and for 6 Incurved blooms, Mr. BENNETT being second in each class.

Mr. J. W. HESSEY, Matford Lodge, Exeter, with splendid exhibits of the dainty blooms, won 1st Prizes for 6 vases of Pompons and for 6 disbudded Pompons. In the former class the vases of Black Douglas and Mme. E. Dordan were particularly good.

Single-flowered Chrysanthemums made an excellent display. Mr. J. S. KELLY had the best display on a space 8 feet by 3 feet, and also won 1st Prize for a vase of singles, both with unusually good blooms of such varieties as Addie Mason, Nerissa, and Edith Pagram. Mr. H. BUNCHMAN was 1st for 6 vases of Anemone singles and Mrs. CHALMERS was equally successful in the class for 6 vases of large singles; the blooms of Bertha Fairs, Alberta, and Caledonia were magnificent.

The large vase of exhibition blooms arranged for effect by Mr. J. S. KELLY fully deserved the 1st Prize awarded it.

The only dinner-table decoration was by Mr. A. PORTER, St. Albans, who was awarded 1st Prize and received similar reward for a large vase of Chrysanthemums. The class for a vase of 5 blooms of any Japanese variety was a good one, and here G. BLAY, Esq. (gr. Mr. C. Pullen), Raynes Park, won 1st Prize; 2nd, Mr. F. CLARK, Chingford. Dr. HORNE (gr. Mr. E. Colman), Colley Manor, Reigate Heath, was awarded 1st Prize for a vase of single Chrysanthemums.

In the Amateurs' Sections Mr. G. BLAY was especially successful. He won 1st Prizes for (a) 24 Japanese blooms, (b) 6 Japanese distinct, (c) 6 Incurved, in three varieties, and (d) 6 vases of Singles with highly creditable exhibits in each class. Mr. J. W. HESSEY was 1st with 3 vases of Singles and 3 vases of Pompons.

KNEBWORTH HORTICULTURAL.

OCTOBER 26. The Knebworth Horticultural Mutual Improvement Society held an exhibition of fruits and vegetables in the local Council schools on the 26th ult.

The exhibition, which was well attended, was opened by Sir Richard Winfrey, M.P., Parliamentary Secretary to the Board of Agriculture. Sir Richard stated that he had been asked by Mr. Prothero to congratulate the Knebworth Society, and at the same time express the hope that they would continue in the work they were doing. The principal prizewinners were Messrs. Darby, Allen, Sexton, Peacock, and Barker.

Honorary exhibits included fine collections of fruit and vegetables from the Earl of Strathmore and from C. A. Cain, Esq., J.P., respectively.

At the conclusion of the prize distribution the vegetables and fruits were sold by auction. One dish of Pears sold for £10. The sale realised £70, which was given to the Welwyn Cottage Hospital.

CROPS AND STOCK ON THE HOME FARM.

HARVESTING MANGOLDS.

THE Mangold crop this year is variable: in some districts the yield is excellent, whilst in others many plots are failures owing to the ravages of the Turnip fly, which, for the first time in the experience of many farmers, killed the whole of the plants, and in many others, partially destroyed the crop. In the South of England and the Turnip and Swede crops are poor; indeed, on many farms there are but scanty plants, owing mainly to the drought experienced at the end of June and early in July.

With the absence of Turnips the Mangold crop should be doubly valuable, especially to sheep farmers. In some fields the roots are exceptionally large but whether a thin crop of large roots is equal in point of weight and quality to more numerous medium-sized roots is an arguable question. Personally I favour the larger crop of smaller roots, believing the extra large roots contain more water than medium-sized, more solid specimens.

We had our first frost—6°—on October 1, and more frost may be expected at any time. It will therefore not be wise to risk the loss of a part of the crop from this cause. Some say that frost does not injure Mangolds in a heap, even though they are frozen, provided they are allowed to become thawed without interference. My experience is that frozen roots do not recover.

FIG. 76.—CLAMPING MANGOLDS.

Mangold roots are easy to pull, as they leave the ground readily. The most expeditious method of lifting them is to seize the tops some 3 inches from the crown with the left hand, and with a large knife sever the leaves within an inch or so of the crown; with the same action throw the roots into heaps or in rows, dropping the leaves close to the heaps or rows. The common plan is to build cone-like heaps of about three wheelbarrowfuls, and cover them with the leaves, which are supposed to be sufficient to ward off several degrees of frost. Usually the heaps are allowed to remain a week to dry, and are then supposed to be in a better condition for storing than when put straight into a heap as pulled.

Last season I lost many roots owing to frost affecting them while in these small heaps, or before they were finally covered in the clamp, and I am adopting another plan of storing them this season instead of allowing them to remain in heaps. I am carting them at once into clamps or sheds. The apex of the clamp will be left open some weeks after it is made to allow heat from fermentation to escape before finally covering with soil. Where frost-proof sheds or barns are available no method is more economical in labour than storing them therein, and in no way do the roots keep better, even though the heap is as much as 10 feet deep. With this quantity the building should be well ventilated for some time after storing to allow water vapour to escape. Where such convenience does not exist recourse must be had to the old-fashioned method of clamp building, which can be adopted by anyone, and there is no better system of storing when it is properly carried out. Usually the clamps are made in the field where the roots are grown to save cartage. Select a site as near to the gate as possible, and preferably on the side sheltered from north winds, as this necessitates less protection from that quarter. The width of the clamp may vary according to the quantity, from 6 feet up to 9 feet; build the roots in cone shape to a point, using the larger Mangolds for the walls. The most expeditious method is to tip the cart up in the middle of the heap, working from the centre of the heap in two gangs to the opposite ends (see fig. 76). When the heap is complete, cover with straw, or what is better, Barley or Oat caving which lies closer together and wards off more frost than straw alone, as this is loose, and naturally admits more air. A covering of straw will tend to keep the caving dry, as when dry it is not so liable to frost penetration as when wet. A coating of soil 1 foot thick, dug from a trench made the clamp, should be put on three parts of the way up the clamp, leaving the apex open for at least a month to allow atmospheric moisture to escape. After that period the whole may be covered with straw and soil, introducing ventilators on the top of the ridge at every 3 feet. Four inch drain pipes arranged on the top of the ridge answer well. Where an abundance of straw is available, thatching answers equally as well as the soil covering, and this method is perhaps a saving of time and labour, and certainly keeps the roots dry. When properly protected Mangolds will keep sound until August. *E. Molyneux.*

Obituary.

John Spalding Lindsay. The many friends of this well-known gardener will be sorry to learn that he died on October 18, at Church Road, Richmond, Surrey, in his 76th year. Born in Dundee, he began his gardening career in Lord Kinnaird's garden at Rossie Priory, where, after serving the usual term of apprenticeship, he moved in turn to Kilmaron, Barrington, and Dunmecht, where gardening was then carried on with spirit. Wishing to gain further experience he next crossed the border and gained experience in some of the best gardens of the day, eventually settling down in the R.H.S. Gardens at Chiswick, from whence he was appointed to the post of head gardener at White Lodge, Richmond Park, where, for 33 years, he managed the gardens, most of the time for H.R.H. the Duchess of Teck. He retired in 1902 to enjoy a well-earned rest.

Although comparatively unknown to present-day gardeners, Mr. Lindsay was well known to the elder generation, by whom his well-balanced judgment and high principles were much appreciated, and his services were eagerly sought after as a judge at the principal flower shows in the county. He was one of the original members of the Richmond Horticultural Society, and, as long as his health permitted, was a regular attendant at its meetings.

The remains were laid to rest in the Richmond Cemetery (beside those of his wife) on October 23, amidst many manifestations of keenest regret at the loss of a dear friend. The Queen was represented by Lt.-Col. Dugdale, the Presbyterian Church of which he was an Elder was represented by Elders and Deacons, and the Richmond Horticultural Society by several members of the Committee. *J. F. McLeod*

ANSWERS TO CORRESPONDENTS.

NAMES OF FRUITS: *J. W. B.* 1, Waltham Abbey Seedling; 2, Mannington Pearmain. — *Miss Cruttenden.* 1, Dumelow's Seedling; 2, Golden Noble; 3, Blenheim Pippin; 4, Court of Wick; 5, a deformed fruit, not recognised; 6, Calville St. Sauveur. Will Miss Cruttenden please communicate with the Editors, as a private letter was enclosed with the Apples and no address was given.—*W. F.* A local and unnamed seedling; the fruits are badly infected with Apple scab (Fusicladium dendriticum).

NAMES OF PLANTS: *C. G.* 1, too withered to identify; 2, Circis siliquastrum; 3, Euonymus europæus; 4, Buxus balearica; 5, Indigofera tinctora; 6, Ruscus aculeatus; 7, Osmanthus ilicifolius; 8, Clematis paniculata; 9, Thuya orientalis var. aurea; 10, Pyrus Aria; 11, Berberis vulgaris atropurpurea; 12, Cryptomeria elegans; 13, Ruscus racemosus; 14, Eleagnus pungens aurea variegata; 15, Aristotelia Maqui var. variegata; 16, Griselinia littoralis; 17, Eleagnus pungens aurea picta; 18, E. macrophylla.—*G. M.* Juglans nigra—the Black Walnut.

OLD MUSHROOM BED: *Mrs. E.* The Mushroom bed will be useless for the further production of Mushrooms. Make up a new bed with fresh material, and use the old Mushroom bed manure for vegetable crops or for the Roses.

ONIONS: *Ognon.* The Onions are foreign varieties and their shape is probably affected by packing. 1, not recognised; 2, Yellow Southport Globe; 3, White Southport Globe.

PESTS ON ASPIDISTRA ROOTS: *Perplexed.* Judging from your description the maggot-like creatures in the soil among the Aspidistra roots are the grubs of an Otiorrhynchus—probably the Vine Weevil, and not Mealy Bug. Submerge the pot in tepid water for 24 hours, and most of the grubs will die from lack of air. Another plan would be to shake the roots free from the old soil and repot in fresh, sterilised compost.

TREE FRUITS: *G. H.* The Pear-shaped specimen is Pyrus Sorbus and the red fruited specimen Crataego Mespilus grandiflora, sometimes called Mespilus Smithii and Pyrus lobata. The latter tree is a hybrid between the common Thorn and the Medlar. The fruits of both trees are wholesome, but not often used for food. It is probable that their best use would be for the making of jelly.

THE SURVIVAL OF WEED SEEDS.

THE old distich

"One year's seeding,
Seven years' weeding"

expresses a greater measure of truth than is generally realised. Every gardener knows that at any time weeds are allowed to run to seed a seed freely there will be trouble for years after, entailing great expense and labour to rid the soil of its undesirable occupants. The reason for this lies in the practical behaviour of the weed seeds. If they were all to start into growth together the season after they were shed it would be possible to effect a clearance once for all, but this does not happen. A certain percentage of the seeds remain dormant in the soil for varying periods of time and often only germinate after the lapse of years.

The duration of this resting period is determined either by a natural tendency of the seeds or by the fact that some of them are buried in the soil under conditions that are not suitable for germination, so that growth cannot begin. If circumstances are favourable and the seeds remain near the surface of the soil, the bulk of them begin to germinate as soon as the proper season comes round. In many cases, especially among leguminous plants, hard seeds occur which fail to grow at first but spring into activity at irregular intervals, thus keeping up a succession of weeds from a single sowing.

A more prolific source of trouble, however, probably arises from the burial of seeds at various depths. In the course of cultivation by trenching, digging and hoeing, the relative position of the particles of earth is constantly changing, and a clod of surface soil, full of resting weed seeds, may be carried down to a depth of several inches or even a couple of feet. Worms also are very active agents in carrying down the seeds. Very small seeds, such as those of Poppy, Pimpernel, Shepherd's Purse, and Groundsel, cannot grow if they are buried more than an inch or two, and if any such individual does attempt to germinate, the little seedling perishes forthwith, from sheer inability to force its way through the overwhelming mass of earth above it. Larger seeds, as Charlock, Black Bindweed and Convolvulus can grow satisfactorily from a depth that is impossible to the tiny seeds, but farther down even these are forced into a state of quiescence. As time goes on many of them succumb and rot, but a decreasing percentage resist all the influences tending to decay, and retain their power of growth in some mysterious way, waiting patiently for an opportunity of fulfilling their proper destiny.

These buried seeds are the ones that give so much trouble as the years go on. The same processes of cultivation that carry down the new seeds to the lower depths bring up the dormant ones to the surface, where the conditions of moisture, air and warmth are such as to encourage growth. Year after year these processes of burial and exhumation go on, and even though no fresh weeds are allowed to fruit, the surface soil is kept provided with a stock of seeds ready to carry on the species if they are undisturbed.

The length of time these buried weed seeds can retain their power of growth is a matter of great practical importance. Various ideas on the subject are rife, but many of them give estimates that are probably much exaggerated. It is an undoubted fact that when grass land or old waste land is broken up large crops of such weeds as Charlock or Poppy are wont to appear. The origin of these seeds is in many cases still a mystery as it is not always possible to show that the land in question has ever been under the plough. In many cases, however, a previous history of cultivation can be proved, and then it is quite feasible that the crops of weeds have arisen from long buried seeds.

Some experiments recently carried out at Rothamsted have proved conclusively that seeds of some common weeds of cultivated land can survive even when they are buried in soil that has been laid down to grass for periods so long as fifty-nine years. Couch, Knot-grass, Field Speedwell, Charlock, and Black Bindweed were among the weeds that sprouted from an old cultivated field that was turned into a meadow in 1856. Part of this meadow, as Gooseacott Field, was grassed over in 1865, so that it has not been ploughed for more than thirty years. Nevertheless there is a large number of living weed seeds at present. From a cubic foot of soil 1 foot square by 1 foot deep seventy four such seeds were hatched, every one of which germinated and produced a healthy seedling. No fewer than fifty-two of these were seeds of Knot-grass, but Pimpernel, Speedwell, Couch and Poppy were well represented, and Black Bindweed, Wild Pansy, and Field Speedwell occurred in less quantity. An examination of the old records of the history of the field shows that these weeds were present when the field was under arable cultivation previous to its conversion into pasture, and that Knot-grass was exceedingly abundant being one of the worst weeds among the crops. In such a case as this the greater number of the arable weed seeds are found at some depth in the soil, most of them being from 5 to 12 inches below the surface. Originally, of course, these seeds were also abundant in the surface soil, but in the course of years they have disappeared from various causes. Under such circumstances a certain number are carried down by earthworms or gradually washed down by rain through the cracks and crannies of the soil, but most of them start into growth only to find themselves crowded out of existence by the new surface vegetation. In this way, as time goes on, the store of seeds in the top soil is depleted. The lower depths of soil, on the contrary, are not favourable to germination, and the seeds that are buried there have no inducement to begin growing. As was mentioned before, large numbers of these seeds rot, but a certain proportion retain their vitality and are able to start into growth if their environment changes to one that is suitable for germination.

While these experiments have shown that seeds of certain kinds of weeds can survive burial for sixty years, it must not be assumed that this represents the limit of time that life can be maintained under such conditions. More evidence of a direct nature is needed, but sufficient data has been collected to show that the buried weed seeds may constitute a very real danger to the farmer and gardener when grass land is broken up or when land already in tillage can be worked more deeply than usual. The history of grassland is often uncertain, the lower depths of cultivated land may have remained undisturbed for generations, so that it is impossible to foretell the results of interference. It is therefore most essential that careful watch should be kept when such interference takes place, as otherwise it may easily happen that very troublesome weeds may regain a strong position from which it will be difficult to extirpate them.—*Horace T. Brandley.*

ORCHID NOTES AND GLEANINGS.

CATTLEYA VALENCIENNES.

HYBRID Cattleyas with *C. Bowringiana* as one of the best parents are invaluable for flowering in autumn and winter, producing a profusion of brightly coloured blooms when out door flowers are almost over.

The latest addition to the class, raised between *C. Dowiana aurea* and *C. Mrs J. W. Whiteley* (*Bowringiana* × *Hardyana*) by H. T. Pitt, Esq., Bessina, Stamford Hill (gr. Mr. Thurgood), and now flowering in his gardens, brings a distinct improvement into this useful section.

A flower sent us resembles an enlarged form of *C. Mrs J. W. Whiteley* or *C. Mantinii* (*Bowringiana* × *Dowiana aurea*), but the lip is broader and more flatly expanded, its undulated margin disclosing the influence of *C. Dowiana* in the last crossing. The sepals and petals are bright purplish mauve; the lip ruby-crimson in the centre shading to purplish mauve towards the margin. There is no yellow disc, but a series of branched, very thin orange lines running from the base to the centre. The column is white, and gives added effect to the general dark tints of the flower.

HYBRID ORCHIDS.

TREES AND SHRUBS.

GARDEN VARIETIES OF CEANOTHUS.

WHILE many of the true species of Ceanothus flower during the spring or early summer, there is a group of garden varieties the members of which bloom from July onwards. These have been raised on the Continent, mainly by the crossing of Ceanothus americanus and C. azureus. This section of Ceanothus is of considerable value in the garden. The different kinds may be treated in various ways. They are very attractive in the shrubbery border, but perhaps the best way to grow them is in beds or masses. A fairly warm soil not too heavy in texture suits these Ceanothuses best, and a light, sunny position is desirable. When grown in beds or clumps a good plan is to prune the plants in February or March. The preceding year's branches may be cut back to within two or three eyes of the base, and any old and exhausted wood cut out, as well as weak shoots. The plants will break freely into growth in due course, and flower profusely during the latter part of the summer. At such times as these, when labour is scarce, some at least of the flower beds might be planted with permanent occupants, notably these Ceanothuses, that is, where they are not given up solely to vegetables. Garden varieties of Ceanothus may be increased from cuttings formed of half ripened shoots inserted during the summer. The cuttings should be placed in a frame kept close and shaded till roots develop. From this circumstance, and the fact that the plants soon attain a saleable size, most of the varieties may be purchased cheaply. They are generally grown in pots for convenience of removal, and when this is the case early spring is a suitable time to plant them, as they have ample time to become established before winter.

The following is a selection of the very numerous varieties: Albert Petit, rosy-lilac; Arnoldii, pale blue; Ceres, soft rose; Coquet form, carmine-pink; Gloire de Plantieres, light blue; Gloire de Versailles, rich blue; Indigo, the deepest blue, but less hardy than most of the others; Ilus Rose, rosy carmine; Lucy Moser, deep blue; and Marie Simon, rose.

The late-flowering Ceanothus azureus grandiflorus has beautiful blue flowers. This is a particularly desirable wall plant; specimens trained to walls will grow to a considerable height, and continue to bloom till the early frosts. *W. T.*

LONICERA TRANSLUCENS, CARRIERE.

THIS attractive bush Honeysuckle is a native of the Himalayas. It is undoubtedly an ally of the well known Lonicera quinquelocularis, but the leaves and flowers are larger, the latter also being a richer yellow. As a lawn specimen or in the shrubbery border L. translucens forms an attractive bush, 6 to 8 feet, occasionally more, in height, and as much in diameter.

It forms a deciduous shrub, producing its yellow blossoms freely in early June, and the flowers are followed in most seasons by numbers of attractive and distinct, transparent, white fruits. At a distance they might very reasonably be mistaken for White Currants during late August and September.

Photograph by E. J. Wallis.

FIG. 77.—FRUITING BRANCH OF LONICERA TRANSLUCENS.

The cultivation of the plants in this country presents no problems. Cuttings root readily in a frame during late summer, and seeds germinate freely when sown as soon as the fruits ripen. The bushes thrive in most soils, but do best planted in positions sheltered from the east, as the tender young growths and flowers are liable to damage by late spring frosts. American horticulturists tell of the beauties of the bush Honeysuckles in flower and fruit in their country, but the sharper contrast between the American winter and summer favours the development and pollination of the flowers. *J. O.*

THE ROCK GARDEN.

VERONICA FILIFOLIA.

ONE adopts this name with some doubt as to whether it should not be V. filiformis, yet it is the designation used by growers who are, if anything, rather pedantic about nomenclature, and it is well known that the names of the plants of the genus are far from well settled. One need not, however, quarrel with the name of filifolia, which so well describes the narrow, beautifully formed foliage. Mr. Reginald Farrer, who has a happy unconventional manner of describing plants, speaks of it as growing "erect into a filmy fuzz of fine greenery, starred with china-blue blossoms," and one can hardly improve upon this description, so well does it denote the appearance of the plant when on the level. In a chink in the wall garden or between the upright stones of the rockery it has a tendency to become somewhat pendent, and looks better in such positions than on the flat. It is one of the most charming of all the smaller Speedwells, and is so easy to cultivate that it deserves the thought of the intending buyer of plants for the rock garden or retaining wall. The plant lasts longer in bloom when growing in a partially-shaded place, and even in a part of the wall garden receiving a mere modicum of sun it flourishes and produces its charming china-blue flowers in a satisfactory way. *S. Arnott.*

NOTES FROM AMERICA.

BIBLIOGRAPHY OF GARDENING.

MR. ROBERTS' letter in *Gard. Chron.*, Aug. 17, p. 71, is a temptation to indulge in further comments on bibliography. In the first place, I may say that the check list I mentioned on p. 57 is a very modest affair, primarily intended to assist in the purchase of books for the Department of Agriculture Library, and arising as an outgrowth or by-product of a very much more extensive project, a comprehensive catalogue of botanical literature, in the widest sense, which was founded by Mr. Frederick V. Coville. The compilation of this catalogue has been carried on for some fifteen years under his authority, and a great proportion of the work has been done by my colleague, Miss Atwood. Of this catalogue we are rather proud, but the horticultural literature is my special care, and, as may be imagined, likely to prove an absorbing hobby. So far as bibliography is concerned, my own aim is that of collecting materials for such work, rather than an attempt to compile anything authoritative. If I could formulate a plan, with any reasonable expectation of its realisation, it would probably take the form of a census of the early horticultural books located in the principal accessible collections of the United States, with information as to first editions where not accessible, and references to critical bibliographical and biographical materials which have been published elsewhere.

There are several very good reasons for limiting my plan to books published before 1800—though, of course, I actually deal at present with a large amount of nineteenth century literature besides. In the first place, while it may seem fairly presumptuous for anyone to attempt the bibliographical study of very early horticultural books where so few are available, as compared with collections in England, it is our very lack of the books themselves which makes exact knowledge of them so acutely necessary. Secondly, the undertaking was not begun early enough to give any assurance of my being able to cover the entire field down to modern times—the horticultural literature published in England alone during the last century would be a "life-sized" task for a bibliographer—and finally, the 1800 limit was happily set for me by the circumstance that American horticultural literature practically began with the nineteenth century, and has been pretty thoroughly covered by L. H. Bailey's "List of American Horticultural Books" in the *Standard Cyclopaedia of Horticulture*, v. 3, pp. 1523-1652. While the latter is, in the strict sense, a mere list rather than a bibliography, it is so nearly comprehensive as to titles that it may well serve as a starting-point for any critical bibliography which may be under-

taken in the future. In the meantime it answers the immediate need as regards American books, and so, while perhaps 1840 or 1850 might have been a more logical point of demarcation for European publications, the initial date of American horticultural literature seems to be the more convenient one for my purpose.

I heartily subscribe to Mr. Roberts' suggestion of the comprehensive bibliography of gardening which might be accomplished by co-operation. While a bare list of book-titles might be a comparatively simple undertaking, such a skeleton is always more or less unsatisfactory to anyone who wants to know about the relationships and peculiarities of books; hence it seems to me that any really thorough bibliography which might be attempted nowadays, would not only be largely annotated, but should include exhaustive references to critical work—all too little at most—which has been done on difficult or interesting books. Such annotation ought, of course, to be in charge of persons richly informed in the history of gardening and the lore of garden literature, and of a topical, rather than a chronological or alphabetical arrangement were followed, it would be possible to distribute this most important task of editorship among those specially interested along different lines—as fruit culture, vegetables, seed trade, fruits, and landscape art. Such a plan would probably result in other irregularities of treatment, but on the whole would bring to the work a measure of sympathy and insight which could more than compensate for the occasional "more feet" and details. A classified card may cover all the technicalities of size, type, indented or flush, full" names and dates of publication, and yet be very unsatisfactory, but a well-kept bibliography has much to recommend it, and I am sure that it would be a very great help to many writers and to others who delight in reading them in that "at the core of gardening."

W. E. Warner.

THE ALPINE GARDEN.

GENTIANA SINOORNATA.

If for no other reason than its late period embracing October and November this brilliant species is worthy of the effort one has to show our still indigent but cultivated list of choicest Alpines. Not new to me, having grown it and seen it on many occasions as a child, it was not till I chanced upon a frame full of it in Mr. Perry's nursery at Enfield dazzling in brilliant in the tidiest sunlight on the last day of October, that I realised what a gem the plant was at its best. At Enfield the species is grown in two positions, sun and shade, and a novice might decide on the instant which of these two situations is the more suitable one. That certain Gentians respond most promptly to sunlight and while apparently revelling in it to the fullest measure, also display their flowers to the greatest advantage, is well known. Of these things there was a clear demonstration. All the plants were growing in pots plunged to the rims, and while involving little or no attention, were obviously in the uniformly cool soil conditions beloved of the plant. Of trailing habit, the solitary flowers terminating the stems are of the size of a small Gentianella. Externally they are marked by a pale cream coloured bands running the full extent of the corolla, a thin line of rich blue passing through each band. When the flowers expand, however, nothing is seen but the brilliant blue. From the cultural standpoint, a mixture of peat, loam and leaf mould in nearly equal parts appears to suit it well, with no lack of root moisture during the season of growth and onward to the flowering period. It will be welcome news to cultivators that these trailing species, inclusive of the new and exquisite G. Farreri, root freely from stem cuttings, a method to be made much of, seeing that much Gentian seed is somewhat erratic in germinating. With half a dozen plants for a start, and half of these used for propagation, a stock worthy of this brilliant Alpine could soon be raised. *E. H. Jenkins.*

HARDY FLOWER BORDER.

CALLIANTHEMUM RUTAEFOLIUM.

The name of Ranunculus rutaefolius has too long been applied to this plant. It is worthy of that of Callianthemum, as it is one of the most beautiful of high alpine plants, with exquisitely cut leaves, like those of the Rue, and of a glaucous hue not easily equalled by those of any other plant. The leaves are almost prostrate, and a little above them rise the white golden centred flowers, of wondrous size for such a dwarf plant. It is one of the finest gems from the higher parts of the alpine regions of Europe and Siberia, where it loves damp places. It is said to be rare in its native habitats, and is quite uncommon in British gardens.

It is, however, easily managed in cultivation and with me grew well on a cool border of rich soil, loam and peat, but likes a sandy soil. I lost it in a very dry season. Where it

THE ALPINE MEADOW RUE (THALICTRUM ADIANTIFOLIUM) WITH SOMETIMES LIGHTLY TINGED WITH PINK.

was difficult to keep in good condition during moisture except through the rain for days, and in dry weather in summer it received a thorough soaking with pure water almost every evening. It responded to this treatment and flowered well annually. My specimen did not increase rapidly, and remained a small plant until it was lost in the cataclysm caused by having to remove to another garden in a dry summer. C. rutaefolium is occasionally increased by division when the plants are large enough, but this method of propagation should only be attempted with great care as soon as flowering is over. *S. Arnott.*

THE MARKET FRUIT GARDEN.

EXTRAORDINARY MARKETING SEASON.

Growers who were lucky enough to have anything to sell will not soon forget the marketing season of 1918, for it is very unlikely that such prices will ever again be recorded. My best gross return for Plums was 23s. per half-bushel of 25 lbs. Very few sold at less than 35s., whilst the highest return was 40s. for Early Rivers. Even Victorias, which are generally the cheapest Plums grown here, made 35s. to 36s. In previous years I have never received more than 8s. per half-bushel for Plums, and that only for a few of the earliest, whilst mid-season varieties have been as low as 2s. 3d., and even went down to 1s. 3d. in 1914. My best return for Apples was 52s. 6d. per half-bushel of 20 lbs. for Allington, other remarkable prices being 50s. for Blenheim Pippin, 40s. for Cox's Orange Pippin, and 36s. for Charles Ross. All these prices were, of course, only for selected fruit, and in each case they refer to one consignment only, so small was the quantity of fruit available. More extraordinary still, perhaps, were the prices ruling for varieties that are usually almost given away. Domino, for instance, almost unsaleable in some years, realised 15s. per half-bushel for the best grade whilst Royal Jubilee, which sold for 1s. to 1s. 6d. in 1914, reached 9s. to 10s. this year. All the above prices are for "firsts" only.

CONTROLLED PRICES.

It cannot be said that the attempt to control prices of Apples met with much success. The fruit of a general controlling order hung over growers' heads for so long, and caused so much

confusion that the greater part of the crop was marketed before the order came into force. As a result, by the time the restrictions were imposed there was hardly any fruit to control. The only people to suffer were those who were local enough to keep late cooking varieties like Bramley's Seedling until their proper season. In fact, the net result of the order was exactly the opposite of that intended, namely, to encourage the early marketing of immature Apples, and force up the price of such varieties as were not controlled. It will be noticed that, in the above-mentioned prices, Allington and Blenheim made more than Cox's Orange Pippin, which is usually much more valuable. That is simply because the first two varieties were sold after the controlling order came into force, whilst Cox's Orange Pippin was sold before.

The marketing season was a short one. Usually I have Apples stored until February and go on selling briskly through November. This year all were sold by the third week in October. Even if there had been sufficient to make keeping worth while, the controlled prices are not good enough to cover probable losses in storage. Marketing of all crops, which started with Black Currants on June 24, lasted just about four months. I have now to look forward

to eight months without a sale. One wonders what would have been the fate of growers in such a season of scarcity if markets had been full of imported fruit, as in normal years.

GREASE BANDING.

Authorities recommend that grease bands should be in position on the trees early in October, as the female winter moths often start to ascend the stem at that time. This year they are late. At the close of the month many males were being caught, these being attracted to the glistening bands at night, but no females of this species had appeared. Several wingless females of the mottled umber moth, as well as a number of the males, were, however, trapped towards the end of the month, and many Apple suckers became victims.

Most makers of banding materials leave purchasers in doubt as to the amount required I find that a 25-lb. box of the so-called grease is enough for 650 trees with an average girth of 15½ inches, making the bands 5 inches wide. This works out at 4 lb. for 26 trees, or nearly 4 lb. per 100. The grease, bought in bulk, costs 2s. 3½d. per lb., and a man was occupied about 5 hours in applying it to 100 trees. At the standard wage of 32s. per week the labour would cost about 5s. per 100 trees, which, with the necessary material, brings the total up to 12s. 2d. per 100, or about 36s. per acre where the trees are planted 12 feet apart each way. There are, of course, plenty of cheaper greases on the market. This particular material, an importation from America, was chosen because it has been found to do no harm when applied direct to the stem, so that no paper bands are required. This means a great saving in labour and some economy in material. Moreover, it can be relied upon to remain sticky up to April, whereas inferior greases dry up and have to be renewed. Lastly, the latter must be applied in bands about 7 inches wide, whilst 5 inches proves all that is necessary with the American grease. Altogether, then, the dearest should prove most economical in the end.

SPRAYING VERSUS GREASE BANDING.

Previously I had not adopted grease banding on anything but a small experimental scale, relying upon spraying to keep caterpillars down. Every spring it is necessary to spray against aphides, and it is easy to make the wash poisonous to caterpillars at the same time. In normal seasons, when caterpillars were not particularly numerous, this plan kept them under sufficiently, and was, of course, very much cheaper than grease-banding. The phenomenal plague of caterpillars during the past two years proved, however, too formidable a task to deal with by spraying alone. The attack develops so rapidly that it is almost impossible to get over the ground fast enough with the spraying apparatus. If we are to expect such hordes of the pests, every possible weapon must be used against them.

Grease-banding will not render spraying unnecessary. It is effective only against the winter moth group, which have wingless females, and these are not the only species that attack fruit trees. Moreover, there are many trees that cannot be banded properly—bush-trained trees, for instance. There must be a stem at least 4 feet high for effective banding. Bands applied 2 feet from the ground catch most of the moths, but not all. Some of the females, it is thought, are carried over by the males. Banding 4 feet up should catch all the females, but some of them lay their eggs on the stem below the band. This does not matter if the grease remains sticky well into April, as the young caterpillars are then trapped as they attempt to reach the branches. Other trees that can hardly be banded are such as have bushes under them, the latter having grown up to the lower branches of the trees. Presumably some of the moths could ascend by way of the bushes. Thus grease-banding has several limitations. *Market Grower.*

A VISIT TO ADMIRAL BEATTY'S GARDENS AT ABERDOUR.

On a beautiful morning, towards the middle of October, I went from Edinburgh, on the invitation of Lady Beatty, to Aberdour House, which is pleasantly situated among sheltering woods above the Firth of Forth, not far from North Queensferry. As I passed over that stupendous construction of modern scientific giants entitled the Forth Bridge I saw, far below, some of the most famous cruisers in the world, conspicuous among these being the *Lion*, whose name will go down to posterity with that of the *Victory*, just as that of her world-renowned Admiral, Sir David Beatty (whom I recently visited on board the *Queen Elizabeth*), will always hereafter be historically associated with those of Grenville, Drake, and Nelson.

Aberdour House, where the Admiral and his lady have made their secluded home, was, I have been informed, a former residence of the Earls of Morton. It looked especially attractive at the period of my visit, nestling among its sheltering woods, with their wondrously transfiguring autumnal hues, in that calm sunset of the year. For it was a benignant day of utter peace, with the sunlight ever and anon stealing out from the pure regions of the slowly gliding clouds, in whose very motion was the dreamfulness of repose, and illuminating the radiant, yet swiftly fading leaves.

In circular borders in front of the mansion-house, and all throughout the exquisite garden, were some of the finest hardy herbaceous flowers, notably Dahlias, Gladioli, and Chrysanthemums, and many perceptibly fragrant, late-flowering Roses (among which Crimson Emblem—a great favourite of Lady Beatty—Rayon d'Or, Constance, and Juliet are usually recognisable) were still in marvellous bloom. Lady Beatty is gradually forming, like Sir Herbert Maxwell at Monreith, and the Countess of Stair at Lochinch Castle, an enviable and grandly representative collection of the "Queen of Flowers," also of Oriental and American Lilies, including many noble specimens of the Himalayan Lilium giganteum, which in a few years will become, in all probability, grandly impressive. Quite close to the picturesque garden, a veritable haunt of ancient peace, the ruins of the old Castle impart a glamour of historic fascination to the scene.

Lady Beatty, after luncheon, at which were present several Commanders of the Fleet, showed me some treasures of the greatest interest, conspicuous among which was a flag of the *Lion* which proudly and defiantly waved from that flagship of the heroic Admiral at the Battle of Jutland, where—

"Serene, amid the thunderous battle-storm,
Where flames of Hell lit up the lurid scene,
Shone, like Trafalgar's Pride, his fearless form,
On those dread heights where Nelson's soul has been.
"In that deep darkening atmosphere of death,
Where men stand calm, to conquer or to die:
Where Hope still lived, and breathed immortal breath,
Flashed the swift lightnings of his eagle eye."

I did not see the Grand Order of the Legion of Honour, which was created by the great Napoleon, as Sir David had that splendid French conferment on board the *Queen Elizabeth*, but I had the privilege of seeing other proud possessions of even greater beauty. Enclosed in a casket with a radiance almost as luminous as their own, were the Imperial Orders of the Rising Sun, presented to the Admiral by the Emperor of Japan.

So ended my first visit to Aberdour House, which, made very memorable by the kindness of Lady Beatty, will ever shine vividly in the regions of remembrance. *David R. Williamson.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Mushrooms.—Very few Mushrooms have been obtainable from open fields this season, but the wet autumn appears to have been unusually favourable to their growth on beds both in the open and under cover. An excess of fire-heat is harmful in the Mushroom-house; this season there has been no necessity to use fire-heat at all. A temperature of 55° is suitable; a higher temperature has a weakening effect upon the Mushrooms and also dries up the beds unduly. There should be no necessity to water a Mushroom bed to develop the first crop of Mushrooms, nor should moisture be given until the first crop has been cleared and signs of exhaustion of the bed are apparent. Success largely depends on having a house which conserves both heat and moisture, as this obviates the need for an early use of the syringe or watering-pot. When water is absolutely necessary, sufficient should be given in a tepid state to moisten the whole bed. A light sprinkling of common salt over the surface before watering will encourage a quick development of the buttons, or the water may be slightly impregnated with salt. A layer of soft, strawy litter placed over the bed will help to conserve both heat and moisture, and nothing more need be done in this direction until the successional crop appears. When gathering Mushrooms, twist them out of the soil, stems and all, as the old stumps are liable to decay and cause a destructive mildew to spread over the whole bed. Continue to collect horse-manure and prepare to make fresh beds as described in former calendars. In preparing the manure, endeavour to get rid of the gases of fermentation without greatly impairing the heating power of the material. Never allow a heap to become saturated with rain, or allow it to remain for a week or longer without turning it, and do not be in too great a hurry to make the bed.

Jerusalem Artichoke.—If not already done, the stems of Jerusalem Artichokes may be cut down to within a foot of the ground. The tubers may be dug if the ground is required, or sufficient should be lifted and stored under the coolest conditions possible to supply requirements for a few weeks.

Brussels Sprouts.—Our earliest plants of Brussels Sprouts are in splendid condition. The seed was sown very early in the spring, and the seedlings transplanted at 3 feet apart in rich, firm ground that has been kept clear of weeds. Planting in loose ground and overcrowding cause the plants to grow tall and the sprouts large and loose. Dwarf Gem is one of the best varieties for all purposes.

Cabbages and Coleworts.—The midsummer plantings of these green crops are in fine condition for use. Coleworts are giving fine crisp heads. This winter green may be planted closely together in late summer when many other crops are over, and should be grown extensively.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire

Strawberries.—At Keele we plunge pot Strawberry plants up to the rims of the pots in a bed of decayed leaves in very shallow frames, and in this position they are capable of passing through the sharpest weather without danger of the pots bursting. Moreover, the soil retains sufficient moisture for a long period without need of water. Some growers stand the pots on vacant shelves in cold fruit houses, but this method involves frequent watering of the roots, especially during dry, windy weather.

Successional Peaches and Nectarines.—The trees of Peaches and Nectarines in successional houses are defoliated, and attention should be given to the cleansing, and, if necessary, painting of the interior of the houses. Winter prun-

ing should be a light operation, it all shoots not required for furnishing the trellis or training next year were cut out directly the last fruits were gathered. If the shoots are trained 4 inches apart they will have sufficient space; it is not advisable to train in much strong wood, rather give preference to medium sized, well-ripened shoots, as these are always the most fruitful. Where large trees have furnished the trellis it may be necessary to prune the leaders back to the next most promising shoot. As soon as the trees are pruned and loosened from the trellis, every portion of glass, iron, and wood work should be thoroughly cleansed, the walls scraped, and coated with fresh lime mixed with a little sulphur. Carefully wash the shoots and main branches of the trees with soapy water, or a solution of Gishurst Compound, 4 ozs. to one gallon of warm water. Scale insects and red spider are troublesome pests, and it is only by stringent precautions that they can be eradicated. The borders will require attention, and where root pruning or lifting is necessary the work should be hastened forward. If the borders only need top dressing, remove a few inches of the surface soil and replace it with compost composed of good virgin loam, old mortar or lime rubble, wood ash, and a sprinkling of bone dust. This mixture will be rich enough to enable the trees to make short-jointed, medium sized shoots. The use of animal manure causes the trees to make rank growth that seldom fruits satisfactorily.

Planting Young Trees. It is advisable to plant a few surplus young trees either in late houses or on outside walls, for replacing old, exhausted specimens. If young trees are not purchased this season, send the order to the nurseryman at once. In selecting young Peach or Nectarine trees, choose those with a clean union between scion and stock, a well developed head of nine to twelve short-jointed shoots, and an abundance of fibrous roots. A trained or extra strong roots should be cut back to sound tissue. Prepare the positions the trees are to occupy in advance of planting, as the sooner they are planted after they arrive the better. The compost advised above is suitable for these trees, and it is not necessary to add bone meal, but the soil should be in a workable condition

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Cattleya and Laelia. Cattleya Bowringiana, C. labiata, and many of their hybrids, including C. Portia, C. Wendlandii, C. Clarkiae, C. Fabia, and C. Mantinii, together with many Brasso-cattleya hybrids, are in bloom. The flowers will remain in good condition for some weeks provided the roots are kept on the dry side, and the amount of atmospheric moisture reduced. Care must be taken that the flowering does not exhaust the energies of the plant, and the spikes should be cut directly the pseudo-bulbs show signs of undue shrivelling. After the plants have passed out of bloom the old spikes and spent leaf sheaths should be removed, severing them as closely as possible to the top of the pseudo-bulb. Moisture sometimes accumulates at the base of the flower sheaths and sets up decay of the leaves and new pseudo-bulbs, hence the need for this operation. The plants at that stage should be afforded a period of rest in the coolest and best ventilated part of the Cattleya house. Let the roots have only sufficient water to keep the pseudo-bulbs plump. Encourage the plants to develop new roots, but premature top growth should be prevented. Weakly specimens should have their flower-spikes removed as soon as they appear through the sheaths. The early flowering C. Gaskelliana, although rooting freely, should not be disturbed by repotting at this season, but this work should be done in the spring, when new growth commences. Plants of C. Trianae that have completed their growth should be carefully watered, affording them only sufficient moisture to keep the roots damp, but the supply may be slightly increased when the flower spikes are seen to be pushing from the base of the sheaths. C. Percivaliana has completed its pseudo-bulbs, and should be kept moderately dry at the roots and grown in a light position near to the roof-glass. C. Lawrenceana makes its growth during the winter months, and is, as a consequence, a difficult plant to cultivate successfully for a period of years. During the winter it should be grown in the warmest part of the Cattleya house, near the roof-glass. The compost should be allowed to become quite dry between each watering; the water should be poured around the outer edges of the soil. From now onwards during the winter discretion should be exercised in supplying water to the roots of all Cattleya and Laelias, for it is far better to keep the plants on the dry side than to allow the compost to become saturated. In collections where numbers of hybrid Cattleyas are cultivated the plants are in various stages of growth at any one time. It is a difficult matter during the winter to keep those that should be at rest from breaking into premature growth. In view of this fact it is advisable to place those that are resting at the coolest, and those that are growing or are commencing to flower spikes at the warmest end of the house.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Salvia Pitcheri. During November and December, when Chrysanthemums dominate in all houses, and in many others, Salvia Pitcheri offers a welcome change. Its velvety blue flowers contrast most effectively with yellow and bronze Chrysanthemums. The plant requires very little attention to make it flower in perfection. After flowering, the shoots should be cut down and the roots plunged in a bed of leaves in a cold frame for the winter. Cuttings should be inserted in the spring in 3-inch pots filled with a light, sandy compost. About 6 or 7 cuttings should be placed in each pot, and they will strike readily in cool frames provided they are kept close and shaded from bright sunshine. When the pots have filled the roots the plants should be potted into 7-inch pots, using a fairly rich compost. During the summer months a Pitcheri should be grown in each of the pots, and the pots plunged in a bed of leaves. The plants will flower outdoors, and in a sheltered position may remain there until October.

Salvia Heeri. The scarlet flowers of this Salvia are produced from the end of January until February. Cuttings should be grown in a light position in the house under conditions similar to those advised for S. Pitcheri. The plants develop a mass of roots, struggling for room in the pots. Feed with weak liquid manure and plants of water and stimulants are needed for the plants are in flower. Tie the growths neatly to their supports.

Salvia splendens. When plants of this species have passed out of flower partly cut them down and place them closely together in a cool house for the winter. The roots will receive very little water until growth becomes active in the spring. If red spider attacks the plants plunge the latter in the beddes and syringe them vigorously with an insecticide.

THE HARDY FRUIT GARDEN

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Alpine Strawberries. Our latest batch of Alpine Strawberries was planted about three weeks ago. When opportunity affords the old beds will be thoroughly cleared of weeds and rubbish, and where late runners are too abundant these will be thinned. On a fine day the hoe will be freely used between the plants. It will also pay to hoe the rows of other Strawberries that have been recently planted. Late runners should be nipped out when working over the beds with the hoe, or possibly with the rake.

Well-Rooted Trees. I recently visited a well known fruit nursery and saw trees being lifted for despatch to customers. I was impressed with the sturdy, short jointed growth of the trees, which, I was informed by the owners, had all been lifted a year ago. Such trees, furnished with plump wood and fruit buds, promised well for moving, and are the best for purchase. Their cost may be a little higher than for trees with less promise for quick fruiting, but the extra expense is soon recouped by quick returns. It may be tempting to purchase trees that are offered cheaply, such as have been grown closely together and that have not been lifted so frequently for their well-being as they should have been. I advise all would-be planters to use discretion and inspect the trees in the nursery before they purchase.

Apple Rev. W. Wilks. This very prolific culinary Apple has been grown at Coinneysbury House Gardens for some years past, and during that period I have watched the trees from year to year with special interest. They are all dwarf trees on the Paradise stock, and being compact and dwarf in growth may be planted 3 to 4 feet apart in the rows, which should be 6 feet asunder; in fact, similar to rows of Raspberries. It is the best early culinary variety for small gardens, as it crops very freely, but it is easy to thin the crops on dwarf trees, and such surplus fruits are always useful for tarts or for jellies and other methods of preserving. The fruits that are left to fully mature will grow to a large size.

Pear Marguerite Marillat. This French Pear is a seedling of Pitmaston Duchess, and is a fine variety to plant in the Apple just alluded to. It forms a close, compact, semi-pyramidal tree. For small gardens, where every possible advantage has to be taken of the limited room, it is one of the best sorts to plant. When the fruits are partially grown they may be thinned and used for stewing. The tree is an almost invariable cropper, with a sturdy growth; do not, however, let it bear to excess, or the fruits will not be of first rate quality. This Pear is very fine growing into a large tree when worked on the Quince stock, hence it may be grown in the same conditions as Rev. W. Wilks Apple. The fruits can also be highly commended for purposes of bottling, being of a better colour than many Pears.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

Bedding Plants. It is not safe to leave Iresine, Coleuses, Alternantheras, and similar plants in frames after this date. They winter well when not too early introduced from frames into a vinehouse kept just above a greenhouse temperature, very little water being required until quite fire heat is used early in spring to induce the growth for the provision of cuttings. A watch must be kept upon the less hardy Caladiums, or they may be caught by a severe frost. A warm, growing temperature is also unsuited to these plants, causing them to make spindly growth. Pelargoniums (Geraniums) in boxes winter quite well with little fire heat, and will even withstand a slight frost provided they are kept quite dry at the roots. As soon as Violas, Gazanias, Nepeta, Lavatera Olbia, and other cuttings in cold frames are seen to be rooted they should be given the maximum of air, but be protected from rain.

Shrubs and Shrubberies. The planting of shrubs should be completed forthwith. In my experience it is really too late, and the few that I had to plant this year were got in early in October, and no doubt are now forming a fresh root system. It is possible, in the case of rough shrubberies, whose purpose it is to hide unsightly objects or provide screens, to prune the shrubs roughly at this season, removing or shortening an encroaching shoot here and another there. Leaves may then be raked into heaps around the roots of the plants, and a little soil scattered over them to keep birds from scratching. Where shrubberies are dug the leaves may be applied now, and leaves and weeds buried in the process.

Lawns. If there be time to spare after sweeping and removing fallen tree leaves, all rough grass that may have escaped cutting should get a final trimming, and all edges to flower beds and borders be straightened; geometrical beds should be reduced to their proper form. This can be done when ordinary ground work is impossible by reason of unsuitable weather, and is a vast saving of labour in spring, when much other work is pressing. Now is also a suitable time to plant out Foxgloves and most kinds of bulbs on those portions of lawns and under trees where they will afford an added beauty to the grounds. Weeds on paths and carriage drives should be removed, giving each plant a gentle twist when pulling it up, in order not to disturb the gravel.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unasked communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 18—
National Chrys. Soc. Floral Com meet., Essex Hall, Essex Street, Strand. Fr. Com. at 35, Wellington Street, W.C., at 6 p.m.

TUESDAY, NOVEMBER 19—
Royal Hort. Soc. Comis. meet

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 42.2°

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, November 13, 10 a.m.: Bar. 30.4; temp. 48°; Weather—Dull.

The Dawn of Peace.

The prospect of peace dawns on a world which has learned to laugh again. It is well that laughter—that antiseptic of the mind—should ring out, and that the old should remember how to smile, for the work which lies before the people of this country requires minds of quad poise, apt to concord and co-operation, and not warped by selfishness or by unmanageable sorrow. Not only as members of the community, but also by reason of their notable contribution to the common good, have horticulturists reason to rejoice. The members of the horticultural trades have made great sacrifices, have sustained uncomplainingly heavy losses, and have submitted with patriotic good grace to many restrictions on their avocations. They, as representatives of a key industry—for without seed there may be no harvest—have (and at times it has been no easy task) provided all the supplies which the country has needed of them. So has it been also with professional and amateur gardeners. When the young were taken, the older professional gardeners, resisting the golden siren call of munition work, continued not only to cultivate their gardens, but have given themselves unsparingly to the work of helping practically the army of volunteer cultivators who, thanks in no small measure to their existence, have made such notable contributions to the food supply. These efforts interpreted in terms of manpower have meant the transport of not fewer —and probably far more than 250,000 American soldiers landed on the soil of France at the critical moment of the war. Nurserymen and florists, too, have lent their powerful aid to food production, and as a recent computation shows, have, in spite of lack of labour, converted over 60 per cent. of their ground and glasshouses to the purpose of food production.

Now that thankfulness fills our hearts for deliverance from the greatest peril that has ever menaced civilisation, we shall do well to remember that our allies will need our help in re-establishing their lives and in rebuilding their horticultural industries. Therefore we can do no better by way of thank-offering than to contribute according to our several means to the fund established by the Royal Horticultural Society for the restocking of the gardens and orchards of France, Belgium and other allied nations. At home, too, it may be that the confraternity of gardeners will be called upon to give practical help in connection with memorial war gardens. For it has been pointed out with cogency that memorials should be wrought in the materials with which those who construct them are apt. And just as we are, as a nation, of only moderate competence in raising statues, we are unrivalled in raising plants: the war has shown that we are a nation of gardeners. Hence what more fitting form of war memorial than gardens in which the people "shall walk abroad and recreate themselves?"

R.H.S. War Horticultural Relief Fund.

The Lord Mayor, SIR HORACE MARSHALL, is presiding at a meeting at the Mansion House, on December 18, when an effort will be made to stimulate the Royal Horticultural Society's War Relief Fund, organised to restore the gardens and orchards of our French, Belgian, and Serbian Allies, which have been completely devastated by the enemy. An appeal is being made to all those who have gardens and orchards in this country to help to restore the gardens and orchards of our Allies. The hon. treasurer is SIR HARRY J. VEITCH, 17, Victoria Street, S.W. 1.

Shrewsbury Floral Fête to be Revived.

We learn from MR. W. G. BRAZIER, Secretary of the Shropshire Horticultural Society, that his society is making arrangements for a Floral Fete and Exhibition, to be held at Shrewsbury in August, 1919. We congratulate our Shrewsbury friends upon being the first to intimate their intention of continuing the work which war conditions alone prevented them from conducting during the past four years.

Horticultural Conditions at Bruges.—In a letter to Messrs. SANDER, St. Albans, Mr. T. MELLSTROM, their manager at Bruges, who remained at his post throughout the war, writes, under date of November 1: "The nursery is not destroyed, but a lot of glass is broken, and we are now busy repairing. In doing this we must take the glass from some empty houses and use it to repair the others. Most of the glass was broken on October 18. Fortunately the weather has been and still is wonderfully mild, but it will take another fortnight to get all the houses done. The Orchids are in a pretty fair state. The Odontoglossums, Cypripediums and Miltonias are best, the Cattleya seedlings not quite as good. There are good Odontoglossum and Cymbidium seedlings, and several houses of Cattleya seedlings. The house in front of the office contains Cymbidium Sanderi and Kentias, and besides that there are other houses with Kentias, also Aspidistras and Azaleas, and then the Bay trees. We have a certain amount of coal and coke, and if the coming winter is not too severe I shall manage to pull through till the spring. January to March, 1917, was the most severe winter I have ever known in Bruges. It was a terrible time, and put us to a severe test. We lost a good many Bays that winter, also all the large Phoenix. The Orchids also suffered that winter and did not get any heat in the following summer, so they could not mature their pseudo-bulbs, and when last winter came, which was also very cold, and the coal of the poorest quality, a great number of the Cattleya seedlings died."

Wart Disease in Potatos.—This disease has now been discovered in the United States. Professor J. G. SANDERS, Economic Zoologist of the Pennsylvania Department of Agriculture, reports it at Hazelton, Pa., and states that it had apparently gained access there previous to the quarantine established by the Federal Horticultural Board on September 20, 1912, prohibiting the further importation of Potatos into the United States. The U.S.A. authorities are taking every precaution to watch and fight the disease, which is a serious menace to the Potato growing industry.

Sugar from Stevia Rebaudiana. In the issue for October 5, p. 140, we published a short note on this subject. We now give a few more particulars. It is claimed for Stevia Rebaudiana that it is the sweetest plant known. Dr. M. S. BERTONI originally described it in the *Boletino de la Escuela de Agricultura de la Asuncion del Paraguay*, ii., 1899, p. 35, under the name of Eupatorium Rebaudianum, with the native names, Caá-èhè and Azucá-caá. He subsequently sent specimens of the plant to Kew for verification, with some information, which is recorded in the *Kew Bulletin*, 1901, p. 175. Further material was received later, and the species was again described by Dr. HEMSLEY and figured by Miss M. SMITH in HOOKER'S *Icones Plantarum*, plate 2816, December, 1906, as Stevia Rebaudiana. Stevia differs technically from Eupatorium in having 5-flowered heads and a chaffy, awned pappus. Dr. BERTONI accepted the correction and adopted it as his own.

The West Indies.—No. 1 of the seventeenth volume of the *Journal of the Imperial Agricultural Department for the West Indies* is devoted almost entirely to the elucidation of the insect and fungus diseases of the Cotton plant in that region. The feeding, breeding, and trapping of certain bugs causing internal diseases are discussed, and remedies suggested. In the same number there are "Some Observations in Fish Poisoning in the British Virgin Islands." Throughout the West Indies fish forms an important article of diet of the inhabitants, and the poorer natives regard it as their staple food. It is recorded that about 100 kinds are commonly caught and used for food. While several kinds of fish are undoubtedly poisonous, others only prove so when not fresh or from ptomaine formation after capture. There is also an article giving the results of experiments on the thymol content of Monarda punctata (Horse-mint) and Carum copticum (Ajowan), cultivated in Montserrat.

Birds and Grain.—The usual dressings used to protect seed corn from birds are made from tar. The different kinds of tar vary in usefulness, and the Food Production Department recently had tests of different tar dressings made at Rothamsted. No dressing tested gives absolute protection; most of them injure the seed unless carefully used, but when Wheat is sown late in the autumn, or grain is sown early in spring, rooks and other birds may cause so much damage that seed should be dressed. The best form of tar that has been tested is acetone tar. This is only supplied by the Ministry of Munitions (Propellants Branch, 32, Old Queen Street, London, S.W. 1), and in quantities of not less than one barrel (40 gallons). It is produced in Essex, and in the Forest of Dean, Gloucestershire, and the current price is about 80s. per barrel at the works. To secure this product growers who do not require a 40-gallon cask should combine and secure delivery of a barrel through a dealer. The method of treatment is to sprinkle 1 pint of tar on 4 bushels of grain, and to turn the seed over and over until the tar

uniformly distributed. If spread out the seed should dry in a day. If the tar is too thick for handling (as it is in very cold weather) it should be warmed before use. This may be done by standing the vessel containing the tar in hot water. Ordinary coal tar is often used for dressing seed, but it is rather variable in nature. It is not so protective nor so safe to use as wood tar. It, however, the coal tar usually met with is used as follows, the risk of injury to seed is slight. One pint thinned down with one quarter to one-third its volume with paraffin and stirred well may be applied to six bushels of grain in the same way as acetone tar. Great care must be taken to obtain an even distribution of the tar, otherwise it will have a harmful effect on the germination of the grain.

A New Violet. The beautiful new Violet illustrated in fig. 79, named Mrs. David Lloyd George, received the R.H.S. Award of Merit on the 8th ult., when exhibited by the raiser, Mr. J. J. Kettle. The petals are deep violet-purple with a few darker markings at their bases. In the centre are four white petaloid stamens, forming a light-coloured eye, and a few violet lines appear on each of them. The segments of the blooms are overlapped, and are regular, together with the compact and sturdy stems, makes the variety a decided acquisition to the finest of recent new Violets.

Stephanandra Tanakae. [illegible] seeds of this Japanese shrub have [illegible] and on the market, and the well-[illegible] its popular name of Japanese Nut. The Stephanandras have no claim [illegible] the edible nuts, but "Japanese Nut" is a good [illegible] name, so we decide [illegible] *Stephanandra tanakae* to the flora of our gardens and notably those in our gardens. The species S. flexuosa and S. [illegible] are [illegible] arguments and claims both [illegible] and graceful shrubs, [illegible] branches. The [illegible] splendid collection of cut [illegible] exhibited by Messrs. J. Cheal and Son, at the meeting of the Royal Horticultural Society, October 22 last. Although Stephanandras [illegible] shrubby Spiraeas or [illegible] Stephanandra flexuosa, the [illegible] are referred as flowering shrubs. They blossom freely, but the individual flowers are dull whitish. The chief garden value of both species lies in the graceful pose of the branches and the warm, brownish golden winter colour of the twigs, which is best seen after the leaves have fallen. Although these shrubs cannot be classed with Vaccinium pallidum, for instance, which develops glorious autumn colouring, yet the leaves of the Stephanandras are very attractive before they fall, and brighten considerably the front of the shrubbery at this season. Wherever the shrubby Spiraeas thrive, Stephanandras may confidently be planted.

War Item. We regret to learn of the death of 2nd Lieut. Jack Hardy, the younger son of the late Mr. George Hardy, of Pickering Lodge, Timperley, and Mrs. Hardy, late of 45, Fitzjohn Avenue, N.W. Death occurred on October 21 from pneumonia. The late Mr. George Hardy was well known as an Orchid lover and grower, and Cattleya Hardyana first appeared in his collection.

Publications Received. *Journal of the International Garden Club*, September, 1918, New York. (Waverley Press, Baltimore.) BUD VARIATION IN POTATOS.*

(*Concluded from p.* 190.)

So far I have dealt with facts which are familiar to all. But the question will, perhaps, be asked: "Granted that no new and distinct Potato—or variety—has hitherto arisen by bud variation, why should that fact rule out the possibility of Nature asserting her independence, and any day, in any garden or field, giving rise (i.e., giving birth) to an absolutely new Potato by bud variation?"

There are two answers that naturally occur to one, namely:

1. That as the processes of Nature are but imperfectly known to us we cannot limit the possibilities of what Nature herself may see fit to accomplish; but, on the contrary, as Nature allows us opportunities of studying her operations, and we are thus able to form some accurate idea of those natural laws which seem to be her guide, we are justified in concluding, not only that what has been will be, but also that what has *not* been is not likely to occur.

2. That the study of the life-history of the Potato affords abundant reason for believing that the possibilities for any such unprecedented and spasmodic action on the part of Nature is inherently improbable.

I need not dwell upon the first answer, but the second deserves attention, for therein lies our strongest ground for disputing any claims that have been made for the origin of any new and distinct Potato by bud-variation, and for demanding duly attested evidence of the data upon which the claims are made.

In the first place, it is significant that the so-called new and distinct varieties are said to have had their birth during the very brief period—say two to three weeks—when the tubers which gave rise to them were buried in the ground, and observation on our part was impossible.

Why should a new and distinct variety arise just at this particular moment? We all know that if any departure from the original form were to take place, it must probably be when Nature would be putting forth her greatest effort; but during the few weeks below ground the tuber may be said to be gradually awaking from its dormant condition. From the moment, however, the foliage appears above ground, all the energies of plant life are stimulated into activity by aerial growth, and it is during the four or five months of summer and autumn growth that we should naturally look if at any time for the gradual signs of bud variation which might give rise, if at all, to a new and distinct variety. But has anyone ever seen an instance of this?

Then, again, we must bear in mind that if bud variation were so at work, it would affect not the whole but only a portion of the plant, perhaps one stem, or more probably one lateral shoot from one of the stems of the plant, just as we may often see a side shoot of a variegated

Fig. 79.—Violet Mrs. David Lloyd George.

* "Do Potatos Give Rise to New and Distinct Varieties by Bud Variation." Paper read by Mr. Arthur W. Sutton, J.P., at the Ormskirk Potato Conference, October 31, 1918.

Holly-bush more or less coloured than the other shoots, or similarly in the case of Chrysanthemums or Roses, when a colour-sport has occurred.

But those who claim that new and distinct varieties have arisen by bud-variation assert that, from the earliest stages of growth above ground, the so-called new varieties are wholly and completely distinct from their neighbours in the plot.

It is important to remember that if Nature was actually developing a new and distinct Potato by bud variation, in the manner which I have indicated as the only one at all conceivable, namely, by bud-variation at or from a single bud on some portion of that plant, we could not possibly expect to find all the tubers produced at the base of that plant had been affected by this process—the probability would be that not more than one or possibly two tubers would differ from the original form. The fact, however, that we have been advised not to remove plants which we call "rogues" from a crop of Potatos, because they may be new and distinct varieties which have arisen by bud variation, immediately gives the lie to the whole claim, as in every instance where it is said a new variety has so arisen the whole of the tubers at the base of the plant, when lifted, differ entirely from the rest of the tubers in the plot, and, moreover, are all like one another.

It has been said that Darwin, in *Animals and Plants under Domestication*, Vol. 1, ch. 2, p. 410, stated that new and distinct varieties did arise by bud variation, but the only instance that can be found in his writings, or in quotations from them, refer most distinctly to changes in colour such as I have already alluded to. Darwin does say that one such Potato which had varied in colour produced a heavier crop than the original form, yet this does not substantiate the claim made, for the tubers which varied in colour might the next year, when the heavier crop was noticed, have had more favourable treatment than the others grown alongside.

But we must go back a step further to find the source of true variation, i.e., variation that would give rise to a fresh individual, or a new and distinct variety. Nature is one in all essential points, and the only source from which any new form can arise or does arise, is to be found in that process of Nature which commences with the fertilisation of the female organ and, followed by the embryonic stage, gives rise to a new birth. By this means, and this means alone, do we find that the innumerable forms around us have arisen, whether in the plant or animal world. I am perfectly safe in saying that in precisely the same manner as we all recognise that no two human beings are the same, and no two varieties of Potatos, however much they resemble one another, are the same, so we have no record of a single instance where any individual, whether plant or animal, has ever lost its identity, nor has its identity been merged into that of another distinct individual during the brief course of its existence.

Another interesting line of study is the comparison of the pollen grains of the wild types of Solanum and the pollen grains of the cultivated Potato. In every wild type of Solanum so far examined the pollen grains are of one uniform type, i.e., elliptical in shape. All the seedlings of these wild Solanums are as absolutely like the parent plant as are Potatos which are propagated by planting sets or seed Potatos. On the contrary, the pollen grains of any and every cultivated Potato are totally different and are irregular in form, and, as we all know, no cultivated Potato has ever given seedlings which exactly reproduce the parental form, even though they may to some degree present a family likeness, and yet the seedlings invariably retain their individuality when propagated by sets.

It may be objected that I am attempting to prove too much, because there have been Potatos put on the market which were stated to have been seedlings from a well-known Potato, and yet when planted side by side with the supposed parent they proved to be indistinguishable from it. The answer, however, must be that more evidence of the actual origin of the so-called seedling is necessary before we can accept the claim made. It is even possible that inasmuch as Potato tubers which are planted for any crop are generally called "seed" Potatos, this term "seed" Potato might by some dealers be considered as a sufficient excuse for describing as seedlings any plants raised from such "seed."

If it is asked: Why, then, is it ever supposed that plants which differ from others in a crop of Potatos have arisen by bud-variation? The answer is that it is not sufficiently realised how difficult it is to obtain any large quantity of seed tubers absolutely true to name, and amateurs, planting the seed they have bought, too often imperfectly, "rogued" during growth, and sold without sufficient expert hand-picking of the tubers, are surprised to find stray plants differing entirely from the general crop, and the inference they draw is that distinct varieties have arisen by bud-variation. The introduction of stray tubers of Potatos in the manure applied to the land is also a frequent source of "rogues" which may appear in crops.

This inference is, perhaps, in some cases encouraged by the misleading term of "seed" Potatos, for it might be argued that if new varieties occur amongst other plants grown from seed why not amongst crops of Potatos grown from so-called "seed" Potatos? The answer, of course, is that the term "seed" Potatos is a misnomer, and it is not sufficiently understood that Potato tubers are but portions of the underground stems of the plant of the previous season's growth, and that when these are planted they can but reproduce the plant of the preceding season, of which they remain an integral portion.

I ought not to conclude my paper without referring to one or two of the most noteworthy instances in which it has been claimed that mutations by bud variation have arisen, the claims being supported with a mass of what appeared to be more or less trustworthy evidence. The most notable in recent times was that of the so-called Solanum Commersonii Violet, which a French barrister named Labergerie asserted had arisen from the tubers he had planted of the wild Solanum Commersonii, the tubers of the latter being about the size of a pigeon's egg or smaller, and of a dull brownish purple, and those of the supposed "sport" a dull red colour, often 3 to 5 inches in length, and of an extremely rough and coarse type.

I visited Monsieur Labergerie at his home in the centre of France, and I have never met a man more evidently sincere and honest, nor one who had kept more complete and accurate records of every detail of the work carried out. So much was this the case that at first I felt it almost impossible to doubt the correctness of the conclusion to which he had come, but it was staggering to compare the wild type, with its tiny tubers, and slender foliage growing only from 8 to 16 inches high, with the abnormally coarse and rough tubers of the so-called mutation or "sport" the haulm of which often grew at least 4 feet high. So great a value did Monsieur Labergerie place upon his crop that the entire field of about 10 acres was surrounded by a high fence, and guarded by alarm guns, so set that any thief attempting to enter the enclosure would set them off and thus give warning.

As most of us may remember, the late Philippe de Vilmorin, of Paris, in conjunction with myself, proved conclusively that this so-called mutation was nothing more or less than the well-known Blue Giant Potato introduced by Paulson, of Germany.

So much attention was attracted by the claims made by Monsieur Labergerie that Dr. Pethybridge, on behalf of the Irish Department of Agriculture, instituted an exhaustive series of trials in every part of Ireland, and summed up his report as follows:—

"Slight variations and differences have, it is true, been observed, but as a result of all the observations made it cannot be said that any constant series of differences between these two plants have been established. The difference observed are not specific or even varietal, and are all more than sufficiently accounted for when considered in connection with the widely distant sources from which the original 'seeds' were obtained. They arise chiefly from differences in vigour of the stocks, and are not greater than often arise in plots of any single variety the 'seed' of which has been obtained from such widely scattered centres. While not prepared to state, therefore, that the two varieties are identical, we cannot show any sufficient reasons why they should be regarded as distinct."

The closing words may not convey to us in England quite the clear and definite meaning they might to Irishmen, but if such a series of trials could not show any sufficient reason why the two should be regarded as distinct, we may perhaps accept this as equivalent to saying they must be identical.

The only other case I will mention is that in which the late Professor Heckel, of Marseilles, stated that Solanum Commersonii had given rise by bud mutation to other distinct forms too numerous to mention in detail. I visited the Professor's grounds at Marseilles, but was far less impressed by what I saw there than when visiting Labergerie. Some of the so-called mutations were easily recognised as well-known Potatos of commerce, and the Professor's claim that a liberal use of pigeon's dung had facilitated Nature's efforts to produce the "sports" did little to remove one's scepticism.

But it is not merely that we are without authentic instances of any new and distinct varieties due to bud variation in the ordinary course of Nature. We have records of various attempts to assist Nature, but all without success. We have tried at Reading the following experiments:—

1. We noticed that the shoot from one of the "eyes" of a Potato differed slightly in colour on one side as compared with the other. A shoot was allowed to grow to a length of about 2 or 3 inches, and then removed and planted in case by any possibility the variation in colour of the shoot might indicate some variation in the produce. But this was not the case, and the colourisation, we therefore concluded, was due to the effect of light on one side of the shoot.

2. All the eyes were removed from the tuber, two eyes from another variety were inserted, the tuber was carefully bound up and planted in case by any chance the produce might show some mingling of the two varieties. In the result, however, the Potatos produced were absolutely true to the variety from which the foreign eyes were taken.

ON INCREASED FOOD PRODUCTION.

AUTUMN SOWING OF BROAD BEANS.

Does it pay to sow Broad Beans in November? This is a question which is asked frequently by northern gardeners, and I propose to answer it in this note. The practice is frequently advised by writers living in the South of England, and no doubt, in districts where the winter is genial, Broad Beans may be obtained much earlier by sowing them in the autumn than in the spring. I consider, however, that this advice to sow Broad Beans in the autumn is quite inapplicable in the north, since if such sowings are made, the plants rarely stand the winter, and even if they do, they are much weakened by the ordeal through which they have passed, and give a very poor return.

I favour no sowings of any kind in the autumn and winter, with the exception of a little Spinach

Broad Beans, which can be got in during September or October if possible. I consider, especially in the north where the weather is so very uncertain, that it is advisable to get the ground as clean as possible so as to facilitate trenching or deep digging on all suitable days. The northern gardener has a strong soil to contend with in many cases, and he also has limited time to do the work of digging and trenching, especially as the reduced staffs and the prospect of bad weather and the troubles in labours to need quite as much food, if not more, than those his southern brother works for in genial counties, such as Cornwall, Devon, Dorset and Kent. It is essential if he is to cultivate the land under his control thoroughly, to begin early at least two sections quite clear, in order to permit of his getting out a trench at one end and working counterpartly to the other. This will not be possible if there is much ground occupied with autumn sowings of the kind just mentioned. The reason that autumn sowing is advised is to get Broad Beans early and thus to avoid attacks of the Bean Fly. However, since such treatment has been proved not to pay in the North of England and Scotland, it should be tried very rarely.

Regarding the Bean Aphis, this can easily be kept in check by spraying with a suitable insecticide as the summer approaches, for spring before the fly has badly attacked the plant. Such precaution will repay the gardener better than adopting such a doubtful policy as sowing autumn seed in wet ground in November.

On land very foul with pests a dressing of gas lime at the rate of one pound to the square yard may be given with great advantage, but if this material is not applied at once it may stale and spoil the land for the next crop. A safer preparation is a mixture of naphthaline cake and lime at the rate of one part naphthaline to fifteen parts of lime, and this material may be dug into the ground with perfect safety a week or two before the crops are put in.—*J. F. Hy. Westwood, Eccleshill, Sheffield.*

CITY OF EDINBURGH FOOD PRODUCTION SHOW.

A CORRESPONDENT sends us the following report from *The Scotsman*, and remarks that the show held on the 22nd ult. was a most valuable contribution to the food production propaganda and created great interest in the city. The fine, if not immune varieties of Potatoes was a source of attraction. Plants for exhibits were submitted, set up in baskets and those were parts of the better known sorts, with, at the end of the table, examples of tubers affected with Wart Disease. The Board of Agriculture for Scotland has recently scheduled some desirable areas in Scotland in which only immune varieties are to be planted, and this note has added considerably to the interest. Over fifty varieties of non-immune Potatoes were staged in three dishes of Peas; fifteen dishes of Potatoes; nine varieties of Onions, and two of the standard kinds of vegetables were represented in several dishes of different varieties. The whole was a most interesting exhibit. The Corporation Allotment Holders Association made a good and a fair demonstration of what an allotment holder might expect to produce. The exhibits were all well staged.

Potato and vegetable culture as a subject that appeals nowadays to thousands of people who in the far away pre-war days were content to have these commodities served out to them daily by or through their greengrocer. Edinburgh has not lagged behind in this important matter, and the Public Parks Department of the city are as anxious as ever to instruct the public how to cultivate their allotments and gardens for food purposes. With that object in view there was opened last night in the Synod Hall a food production exhibition. The exhibition, which will be open to-day and to-morrow, is purely educative in its character. It is free to the public, and all the good things that are spread on the tables have been grown on public ground—at Saughton, Portobello, and Inverleith, under the supervision of Mr M'Hattie. Practically all sorts of Potatoes and other vegetables are displayed in a most artistic and attractive form. There are two tables of Potatoes, one immune from disease and the other not immune, and with a view perhaps of impressing on Potato growers the risk of planting varieties belonging to the latter class a few Potatoes are shown in all their loathsomeness with the ravages of Wart Disease displayed upon them. An examination of the Potato exhibits and provide useful hints, for one of each different variety is shown, as the result of tests and experiments, to demonstrate the quality of the Potato what sort of cropper it is, and its liability to disease. The other vegetables make a fine display. The tickets attached to the exhibits show, when planted out, and the season it was. Councillor Mackenzie, the Convener of the Parks Committee, presided at the opening ceremony, and Lord Provost Sir J. Lorne Macdonald, in formally declaring the exhibition open, said he hoped that allotments (they had not started in a war necessity) would become a permanent feature in the city of the city. What would be done after the war in providing the parties that had been put under cultivation would be for the citizens to say, but for himself he thought the cultivation of the land was the finest form of recreation they could have alike as regards its productive, educative, and moral values."

POTATO YIELDS.

WHAT [illegible] *Rep.* 1653 kindly give details as to how the 5lbs. lbs. of Potatos were grown [illegible] as to the soil they were given out to the [illegible] conditions as to planting, and with [illegible] the kind of soil, the amount of manure, and the space of ground that was used. There is [illegible] to [illegible] and [illegible] [illegible] as the records.—*J. P.*

HOME CORRESPONDENCE.

The Editors do not hold themselves responsible for the opinions expressed by our readers.

Planting by Caterpillars [illegible] I [illegible] interested in the feats of worms in drawing [illegible] into their holes as described by Miss S. Carson. The instinct of worms in drawing leaves into their burrows by the stalks is remarkable, because they thus cover the leaves rather than fix the line of least resistance. I have just had the fortune, or misfortune, to observe a similar instance in the case of the caterpillars of the Common Dart Moth (*Agrotis segetum*) and the Heart and Dart Moth (*Agrotis exclamationis*). During September the latter was in a plague [illegible] the former. The latter, known as surface caterpillars, bury their bodies in the soil by day, and come out at night to feed on the most diverse vegetables. They cut the stems of young Cabbages at the ground line, and, detaching the leaves, drag them into the soil by the stalk. The effect is that all the leaves of Parsley plants and those torn into the soil, gradually consuming them under cover. The finely curled blades appeared planted all around the leafless crowns, and by this means I knew where to dig out the caterpillars by day. I had to replant one third of the Cabbages.—*J. F.*

A Prolific Antirrhinum. Last year I received from Messrs. Arthur Turner, Ltd., Penzance, a few tall, yellow variety, with Carmine Queen as intermediate form. I saved the pods. The seeds were sown in February and the plants put out in a bed in my garden some time in April. They grew exceedingly well. They were all tall, the shortest 4 feet to the top of the central flowering spike. The form of the flower in all was near that of Carmine Queen, and not the least like the handsome form of Yellow King. The colour of all the flowers on all the plants was magenta-carmine, with a yellow lip. I am looking forward to next year's progeny with great interest. This autumn I saved a few pods of seed, and it occurred to me to count the pods produced on one plant. The number was 519, and the seeds contained in one pod I counted numbered 410, which gives the enormous total of 150,790 seeds reproduced from one seed sown in February. I have seen figures given for other plants, but never remember seeing any for the Snapdragon.—*W. Cuthbertson, Duddingston.*

Richardia Elliottiana and Pentlandii (see p. 171). In the note accompanying the illustration of four species of Richardia, in the *Gardeners' Chronicle* for October 26, mention is made of the distinguishing features of the two above named. It is stated that R. Elliottiana has spotted leaves and wholly yellow spathes, while in R. Pentlandii the leaves are not spotted and the spathes are dark purple at the base. This is quite correct so far as most individuals are concerned. Some years ago, however, I had the handling of a consignment of tubers sent from South Africa as Richardia Pentlandii. While most of them had the thick textured, dark green leaves characteristic of Pentlandii, a few were spotted exactly as in R. Elliottiana. The flowers of all these spotted forms were purple at the base of the interior; in fact, these individuals were in every way Pentlandii except the spots on the leaves. Circumstances over which I had no control led to these Richardias passing out of my charge, so I do not know what became of them afterwards. So far as my experience of the two species extends, R. Elliottiana is a more vigorous grower than R. Pentlandii. When now they were both commonly referred to as golden-flowered Arum Lilies, and being treated as R. atrocana failures were frequent.—*W. T.*

Tulip Paul Diack. I am not able at this moment to consult any lists of eighteenth century Tulips, but the name of Paul Diack seems familiar to me. For many years I have had on my shelves a copy of the poetical works of the Rev. Edward Young, best known from his once popular "Complaint; or, Night Thoughts." In recently turning over the volume, my attention was arrested by a long passage in the second of the series of satires "Love of Fame, the Universal Passion" (first published in 1725), dealing poetically with the Tulip Paul Diack. Dr. Young considerately furnished, at all events to the later issues of the poem, a very necessary Key, in which we are informed that "Paul Diack, who gave name to a Tulip, was an honest, topping old Citizen of London, and a great Stock jobber." I have found no trace of him in the literature of the eighteenth century. The name, or style of the fact that Paul Diack was a London citizen, seems to be of Dutch or Flemish origin, possibly a corruption of Dyck. Perhaps Mr. Krelage of Haarlem, has some record of the Tulip which commemorates this "honest, toping old citizen of London."—*W. Roberts, 18, King's Avenue, Clapham Park, S.W.*

Apples for Grass Orchards. I can assure Mr. Holmes-Smith that I did not make my selection of Apples for orchards without considerable thought and as the result of experience of only from my own knowledge but observation of other people's practices. I can point to some of the finest trees of Dumelow's Seedling Wellington growing in a grass orchard and on the stiffest of clay soils. Not only do the trees yield large crops, but the growth is all that could be desired. On gravel soil I know of much older trees that are model specimens. What other Apple is there that commands the same price as Dumelow's Seedling late in the season? Much depends on the preparation of the ground and the after attention given the trees. I much prefer Peasgood's Seedling as a standard to Newton Wonder, especially if there is a prospect of moderate after attention in pruning. The former is naturally adapted to orchard cultivation by its compact habit of growth, while Newton Wonder is much more erect in habit, and as I wished to keep down the list of varieties, especially for farmers, I did not include both Newton Wonder and Bramley's Seedling. With regard to Worcester Pearmain, I grant this is not so vigorous in growth as some other varieties, but more money can be made from this Apple than any other dessert variety in cultivation, even with its medium growth. This I considered was a good reason for its inclusion.—*E. Molyneux.*

CROPS AND STOCK ON THE HOME FARM.

SOWING WHEAT.

No time should be lost in pushing on with the sowing of Wheat on any farm where the soil is in suitable condition. No advantage is gained by "muddling" in the seed when the soil is wet, because sufficient harrowing cannot be done to thoroughly bury the grain. In right soil success partly depends upon the ground being made firm as a preventive of wireworm attacks and the upheaval of the plants by frost. Again, in spring, when harrowing and rolling is done to make the soil firm and give a stimulus to the growth, if the soil is loose there is a risk of the harrows pulling up very many Wheat plants, or the roller may bury too many of the blades, and thus smother the growth and reduce the crop.

In the Southern Counties I find Wheat germinating well. Under the tests necessary by law, Wheat seed for sowing must have a minimum germinating power of 90 per cent. The dry August enabled the ricks to be built in good condition, and where thatching was promptly done the corn is coming out in splendid condition, but there are many "pinched" corns, as the result of drought at the end of June and during the early part of July, at a time when the corns should have been filling out.

Many of these "pinched" corns will come out when the bulk is screened, which should always be done, although some growers, I am sorry to say, sow direct from the threshing machine on their own farms. Threshing machines as a rule make excellent work, but they cannot be expected to take out all seeds of weeds- Docks, for example—therefore it is an advantage to winnow or screen the corn before sowing.

Some of the newer varieties of Wheat are not immune from these "pinched" corns, showing that adverse weather has an effect on even the newest sorts. These defective corns reduce the yield in bulk and weight per bushel.

Where the Wheat land was well prepared and the cultivation in all respects first rate, many good yields have been recorded. I had twelve sacks—48 bushels—per acre from one good sized plot of the Red Standard variety. I know this is not an extra good crop, but it is useful for seed, especially as the quality is good. This crop followed summer fallow and Mustard (sown early in August), ploughed in when about 2 feet high; a preparation I think excellent, because the summer fallowing provides such a good opportunity for freeing the land of Couch and other troublesome weeds, which, I regret to see, are on the increase.

Farmers can easily test their own seed Wheat. It is a quite simple matter, where there is a glasshouse. From a sample of seed, as screened, count off one hundred corns, taking them as they come and including the small as well as the large, so that the test shall be characteristic of the bulk. Soak the selected seeds in water for thirty six hours, spread them on a piece of flannel, on a plate, cover with more flannel, which should be kept moist, and keep the plate in a warm room or greenhouse. Germination should take place within from six or ten days, according to the warmth of the room. Forcing should not be attempted, as in moderately warm conditions there will be a natural germination. Count those that germinate, and thus discover the percentage of germination.

Where there is any doubt about the result of the future Wheat crop in any field owing to the lack of manure or suitable cultivation before sowing, it will assist the crop if a dressing of basic slag is given at the rate of 6 cwt. per acre. This is one of the best of manures for Wheat, and it has a good effect on the succeeding crop, especially should grass or Clover be sown with the Wheat for a future Hay crop. There are also the concentrated manures prepared by various experienced firms, which are excellent. *E. Molyneux, Swanmore Farm, Bishop's Waltham.*

TRADE NOTES.

CHAMBER OF HORTICULTURE.

IN point of numbers the meeting of Presidents and Secretaries of societies called to consider the aims and rules of the proposed Chamber of Horticulture, and held at Donnington House, Norfolk Street, Strand, on Tuesday, November 12, was not particularly encouraging, but from the point of view of business done it was a very successful gathering. Mr. Geo. Monro presided, and there were also present Messrs. R. Wynne (Secretary), H. Morgan Veitch, Joseph Rochford, W. Poupart, W. J. Lobjoit, Alfred Watkins, R. W. Wallace, A. Dawkins, C. Page, W. H. Page, G. H. Barr, Alex. J. Monro, Duncombe Gibbs, F. R. Ridley, C. H. Curtis, J. S. Brunton, E. F. Lawes, W. P. Seabrook, Bradnum, Lister, T. Want, H. R. Darlington, and others.

After the preliminary statement by the chairman the meeting was thrown open to general discussion, but beyond a general agreement to eliminate jealousy, suspicion, and consequent friction between societies, and a desire to secure the utmost advantage from the centralisation of force which the Chamber would offer, the discussion turned upon two points, i.e. (1) Whether local societies already in affiliation with a special trade federation should be allowed to attach themselves to the Chamber direct, or through their federation only; and (2) whether non-trading societies, such as the R.H.S. and the national and local floricultural and horticultural societies, should be admitted to association with the Chamber. These matters were discussed at considerable length, and it was finally agreed that societies belonging to a federation should be allowed to attach themselves to the Chamber direct, but it was pointed out that comparatively few of such societies would do so because of the financial responsibility they would thus incur, and societies financially strong enough to join the Chamber might prove a source of strength and inspiration to their federation. It was felt that to prevent societies belonging to a federation from joining the Chamber direct would probably mean that many would secede from their federation.

It was also agreed that to make the Chamber a horticultural one in the widest sense, non-trading societies should be admitted under special conditions to be presently arranged, and in such a way as to safeguard the interests of traders; these non-trading societies to have their own special committee.

Mr. Monro said the original aim in regard to finance was an income of £1,000 a year; this had been assured for five years to come, and the promoters were now aiming at £10,000 a year income, ten thousand pounds' worth of good work on behalf of horticulture, and a central building with offices, library, and meeting rooms. The date and place of the mass meeting will be published in due course.

LAW NOTE.

CLAIM FOR COMMISSION.

MR. JUSTICE SARGANT, in the Chancery Division, was occupied over three days in hearing an action in which the plaintiff—Mr. William Dent, of "Bankside" Cowbit Road, Spalding—sought to claim against the defendant—Mr George Monro, junr., of 4, Lavistock Street, Covent Garden, with whom was afterwards joined Mr. R. S. Cobley, his partner—a declaration that the plaintiff was a partner with the defendant in the business of a bulb farm at Spalding, or in the alternative, that he was entitled to an unpaid balance of commission amounting to about £2,300.

The defendants denied partnership and paid £500 into Court in full satisfaction of the claim for unpaid commission. The claim was made under an agreement for five years, commencing January 1, 1911, under which the plaintiff was entitled, as remuneration, to a fixed commission calculated on the annual net profits of the farm, of which he was defendants' manager.

The plaintiff claimed that upon termination of his agreement the bulbs in stock and plant generally, should, for the purposes of calculating his commission, be valued for the last year at selling prices. The defendants contended that the correct and proper method of valuing these stocks was the usual commercial basis of cost or market, whichever was lower.

Mr Justice Sargant dismissed the action on both counts, with costs against the plaintiff.

Obituary.

Wencelas Cyril Vejvoda.—Mr. W. C. Vejvoda, a Czech gardener employed in the Royal Gardens, Kew, died of influenza after three days' illness, and was buried in Richmond Cemetery on Friday, the 8th inst. Before he entered Kew early this year, Vejvoda had been employed in the nurseries of Messrs. Cibrans, Altrincham, for nearly five years, where he had rendered satisfactory service, and made many friends. At Kew he proved a first-class man. He was clever, industrious, keen after knowledge of plants, a most finished workman in every sense, and although, when he first came, he had to bear that prejudice against the "enemy alien" which has been in the air lately, he quickly lived that down, and by his kindly nature and manliness endeared himself to all who had dealings with him. He had been promoted to the rank of subforeman only a few weeks before he died. W. H.

ANSWERS TO CORRESPONDENTS.

DRYING GRAPES: *P. Y. C.* You will find the necessary details in *Vegetable Bottling and Fruit Preserving*, by Mr. and Mrs. Banks, published by the Royal Horticultural Society.

IRIS LEAF BLOTCH DISEASE: *L. G. P.* Iris Leaf Blotch Disease, caused by the fungus Heterosporium gracile, is widely distributed, and is most serious in plants grown in soils which are lacking in lime. The disease is noticed particularly in late summer and early autumn when the foliage is covered with irregular, yellowish brown blotches, and it is not unusual to find the surfaces of the leaves almost wholly occupied by these diseased areas. Unlike the bacterial rot disease of Iris, the rhizomes are rarely killed, but the plant becomes generally weakened and dies. If one of the diseased areas is examined with a pocket lens a number of black dots will be seen; these consist, for the main part, of masses of spores. These spores (conidia) are attached very loosely, and are readily dispersed by the wind, thereby affecting other Iris plants in the vicinity. Other spores find their way to the ground, and as it has been found that the spores can retain their vitality until spring, the new growths from the lateral buds on the rhizome are open to infection from the soil. It is useless to employ a spray fluid to check this disease, as it is impossible to wet the leaves sufficiently owing to their waxy nature. The following method has been found to be efficacious in eradicating the disease. All the diseased foliage should be removed in late autumn and burned. The ground should then be dressed with slaked lime at the rate of about two tons to the acre. It is not necessary to lift the plants in order to treat the soil. The lime should be forked into the soil directly after application, and it will be found that not only will growth develop clean and healthy in the spring, but it will remain so throughout the season.

MUSSEL PLUM: *D. P.* This is the old Mussel Plum, now seldom seen in gardens, but still used as a stock. It is doubtful whether it is possible to purchase a tree of any size.

NAMES OF PLANTS: *C. A. W., Bucks.* 1, Choisya ternata; 2, Kerria japonica var. variegata; 3, Picea pungens var glauca; 4, Alyssum sp.; 5, Polygonum sachalinense.—*W. M. M. D.* 1, Cattleya labiata; 2, Maxillaria picta; 3, Selenipedium Dominianum, a hybrid between S. caudatum and S. caricinum (Pearcei); 4, Selenipedium longifolium, varieties of which are also to be found in gardens under such names as Hartwegii, Hincksianum, and Boezlii. *J. W. P.* 1, Cheiroden fragrans, H. pl.; 2, Hebeme Soleirolii.

OLD GARDENING BOOKS: *G. B. C.* Your old books by Mawe and Macgillivray are not likely to realise a large sum, but it may be well worth your while to advertise, if you propose to sell them.

ARMY CULTIVATION IN FRANCE.

THE great contribution which the Armies in France have made to food production, both on a large agricultural scale, and on a small scale by intensive cultivation, deserves to be widely known and appreciated.

From small and unostentatious beginnings by certain units, it has grown to a vast undertaking, organised in part through the several Armies, and in part by a Headquarters Staff under a Director of Agriculture, until to-day it is the hobby of the Army in France. As our illustration in fig. 80 shows, even within range of enemy guns not only cultivation but vegetable shows have been carried on with enthusiasm and success.

How great is the good which has been achieved it is impossible to exaggerate; but when the importance of fresh vegetables in maintaining health is remembered, the fact that at the present time the Army in France is supplying itself with upwards of 100 tons of vegetables a day, will show that, as measured in terms of health alone, this cultivation and its results are worth an army corps of doctors. The importation by the Armies in France of Scotch and Irish seed Potatos has, we are informed, resulted in extraordinary large crops indeed, it is stated by those in a position to know that the average yield of main crop Potatos in the fields and gardens under Army cultivation in France amount to 10 tons to the acre. Even admitting that the large supplies of manure which—no longer burned, as was the case often in the early, extravagant days—are available, this average, if it be actually achieved, is a remarkable testimony to the success with which H.M. Forces accomplish everything they undertake.

When in the early days, before Army cultivation became the mode, a large scheme of cultivation was sanctioned by the Army Council, one of the officers to whom it was expounded observed: "But this is more than the Germans are doing"; but when the reply was given, "That is why we are going to do it," he became a converted enthusiast. The remarkable results which have been achieved in France are, of course, due in the first place to the fact that the Armies contain large numbers of the finest growers of Great Britain, so that when men of experience are wanted to take charge of Army agricultural and horticultural operations there is no difficulty in finding them. Nevertheless, when the appalling labour difficulties which a year or more ago beset the High Command are taken into account, the extent of the area cultivated and the quality of the crops produced reflect the highest credit on the Armies in France. Measured in money values even, the vegetables produced in France during the present season are estimated to be worth £52,000, and this at a price of 10 centimes a pound; in as much as the present price of vegetables in France is said to be about 35 centimes a pound, the value of the Army vegetable produce may be placed at over £150,000.

Although it lies outside our subject, the work of cultivation done by the Armies at home must not remain unmentioned. We believe we are right in saying that the area cultivated largely by spade labour by the Armies at home has been increased threefold in the past year, and now amounts to more than 6,000 acres.

It is an interesting instance of the thoroughness with which the soldiers have carried out their work that they have followed the advice of the Food Production Department, and have not neglected to spray their Potatos, with the result that in more than one case the Army gardeners have set an example of good cultivation to their civilian neighbours; and have even protested against the neglect of spraying by those neighbours. Nor has the practice of horticulture been confined to H.M. Forces at home and in France. Wherever they have found themselves in Salonika, in Palestine, or in Mesopotamia they have put in practice the apothegm of Candide, "Let us cultivate our gardens." The fresh food which these part time Army allotment holders have raised has been a powerful means of maintaining the health of the Army, and it is certain that if ever again which Heaven forfend! British armies take the field, they will equip themselves not only with artillery and all the other munitions of war, but also with a cultivation corps.

This is among the things which to the uninitiated seem crazy, but which to those who know anything about the effect of diet on health is only common sense, and it is vastly to the credit of the High Command that the essential value of the apparently unnecessary was perceived so long ago, and orders issued making it possible for armies to become, in part at least, self-suppliers. The successful efforts of the Army Council to promote cultivation have not been confined to the issue of orders. Nearly two years ago the Army Council established an Army Agricultural Committee, under the chairmanship of Viscount Harcourt—who, as our readers know, is a keen and accomplished horticulturist. This Committee has rendered valuable service, with the object of promoting and providing financial assistance to Army cultivation.

The energetic assistance which the Royal Horticultural Society rendered to camps and depôts in France in the early days of the war deserves to be remembered. Thanks to the generosity of the Society several hundreds of gardens were supplied with plants and seeds, and the origin of the present popularity of gardening in France is to be traced in large measure to the forethought and munificence of the R.H.S.

Finally, we would offer the suggestion that if, even when Leagues of Nations have become established, standing armies are still found necessary, horticultural and agricultural practice may be made part of their peace-time training.

ORCHID NOTES AND GLEANINGS.

LAELIO-CATTLEYA MANBEUGE.

A FLOWER of a new hybrid named Laelio-Cattleya Manbeuge, raised between Cattleya Rex and Laelio-Cattleya Ophir (C. Dowiana aurea × L. xanthina), is sent by the raisers, Messrs. Sanders, St. Albans. The bloom has a strong resemblance to that of C. Rex, but is florally far superior to that species, and possesses the clear yellow tints which L. xanthina usually transmits to its progeny. The broad, flat sepals are light canary yellow, and the effectively disposed petals slightly lighter in tint. The base of the lip is bright yellow, the front light mauve-shaded crimson-purple, the margin white, the undulated margin. A series of branched yellow lines extend from the base of the lip to the centre. The pollen masses are like those of Cattleya, and in the form of the flower and its good substance the Cattleya parent dominates.

INTERESTING LONDON TREES.

THE present season will long be remembered as one in which trees have been particularly fruitful. Rarely has the Catalpa produced its spikes of curiously marked flowers in such abundance as during the summer of 1918, trees both large and small rivalling each other in their wealth of bloom. The finest specimen in Manchester Square has never been known to bear such quantities of its ever-popular flowers as during the latter end of July. The Ailanthus has everywhere likewise been unusually freedom, the not very showy greenish white clusters of flowers being in most cases produced in such abundance as to attract attention. Nearly approaching the latter in appearance is the Honey Locust (Gleditschia), which in many parts of London has flowered with unusual freedom. There is a fine specimen in front of the secretary's house in the Royal Botanic Gardens, Regent's Park, is the Caucasian Pterocarya. P.

tuxuntolia), which, near the Victoria Gate in Hyde Park, has been a source of wonder to visitors. The curious, drooping flowers, which hang downwards at right angles to the branches for a foot and more in length, render this one of the most interesting of hardy trees. The largest Pterocarya in London is growing in the City of London Cemetery, where also may be seen a goodly specimen of the rare, black-fruited Thorn (Crataegus nigra). In several of the parks and private gardens the Judas tree (Cercis) has flowered with unusual freedom, in some cases even young specimens have produced the deep, rosy purple flowers which distinguish this species. Rhus Osbeckii has flowered freely in Ruskin Park, where are the only specimens of this rare and beautiful Sumach that I have found in the Metropolis.

The Tulip Tree (Liriodendron tulipifera) is a capital subject for town planting, and may be found in good condition in several of the parks, notably at Golder's Green, where there is by far the largest specimen of its kind in London. Both this tree and the still rarer Liquidambar may be seen in a flourishing state in the grounds of the Royal Botanic Society. Here Battersea, though perhaps equalled by the far-spreading specimen in Waterlow Park, where a healthy, vigorous growing tree has spread laterally to a distance of 30 feet. The Tamarisk by the lake-side in the same park has quite outgrown its normal dimensions, and some of the stems are fully 20 feet high, and girthing 2½ feet at a yard from the ground. The magnificent Hickories in Waterlow Park are by far the finest in London, other species of interest at the same place being the Paper Birch (Broussonetia papyrifera), Honey Locust, and Magnolia acuminata. The fine Mulberry tree, though old and decrepit, is yet making a brave stand for existence, and should, with care, exist for many a year. Here also is a good example of the Maidenhair tree, Ginkgo biloba.

Amongst the many species of Oak, none excels the Turkey Oak for town planting, and in Ruskin Park there is a huge specimen, the stem of which girths 12¼ feet at a yard high, the branch spread being 100 feet in diameter. It is questionable whether a larger tree of the kind is to be found in the County of London—certainly not in the Metropolitan area.

Both the Cockspur and Tansy-leaved Thorn (Crataegus Crus-galli and C. tomentosa) produced an abnormal quantity of flowers, and now show a rich harvest of fruit. The rare and interesting Celtis australis and Koelreuteria paniculata both flowered in Islington Cemetery during the past summer. *A. D. Webster.*

wards they seem to deteriorate and fall an easy prey to disease of one kind or another. That this is largely a question of soil and climate is shown, I think, by the fact that in the garden of my friend, Monsieur Denis, of Balaruc-les-Bains, in the Département of Hérault, several of these Irises, which decline to flourish here, not only increase and continue to flower, but even produce sound seeds. I am indebted to M. Denis for many of the facts contained in the following notes.

There is another circumstance which has vastly increased the difficulty of arriving at anything like a satisfactory account of these white Irises, and that is that in the East, and especially among the Mussulmans, white Irises are frequently planted in graveyards. I am not aware that the custom has any definite religious significance, but it seems to be undoubtedly a fact that I. albicans is a native of the mountains of the Yemen district of Arabia and that it has been carried thence by the disciples of Mohammed almost as far as their religion itself has spread. I. albicans was first described botanically as growing near Almeria, in Spain, whither it had doubtless been imported by the Moors, who took it also into Sicily and into

(See p. 203.)

NOTES ON IRISES.

SOME WHITE POGONIRIS.

OUR knowledge of the various white-flowered bearded Irises is still in a fragmentary and unsatisfactory condition, but it may nevertheless be worth while to put on record such data as have by degrees been accumulated. The investigator into the origin and relationship of the various species and forms, who pursues his enquiries in England, is greatly hampered by the fact that it is extremely rare for the known forms of white, bearded Irises to produce apparently sound seeds in our gardens. Moreover, it is by no means the case, unfortunately, that these white Irises will always continue to flower here. Newly imported rhizomes seem to bring with them sufficient vigour to flower in their first year, but after

Asia, whence it has more than once been sent from Samsun and Mardin, as well as from Persia. From Spain it was apparently conveyed to America, where it has escaped from cultivation and become more or less naturalised in Mexico and in more than one place in South America. It has also spread from Spain to the South of France and given rise to the name of the village of Les Onglous (Provençal for Irises, apparently), a short distance to the west of Cette, on the coast of the Mediterranean. There it grows in millions on the sandy banks among the vineyards, where the vines grow by the seashore to within 20 feet of high tide. M. Denis informs me that the plants, which I took to his garden from Les Onglous, never set seeds, though others have done so here on rare occasions. On the contrary, plants from Mardin, when pollinated from the Les Onglous plants, seed readily, and the seedlings have shown that this Iris reproduces itself from seed without producing any appreciable variations. This is precisely what we should expect of an albino form, and fortunately, in the case of I. albicans, we possess in I. Madonna the purple-flowered species of which it is the albino form. I.

Madonna was introduced from Arabia some ten or twelve years ago, and I do not think that anyone who will compare the growth of these two Irises, will doubt that they are mere colour forms of the same species.

Other albino Irises, such, for instance, as the white form of I. tectorum, breed absolutely true from seed when self-fertilised, and I have little doubt that sooner or later we shall possess white forms of all our purple Irises of the germanica and pallida groups. Some years ago I found in Dalmatia a tall, white pallida, which, however, has a very weak constitution in our English climate, and, though still alive, it persistently refuses to flower here. There is also in existence a white form of the well-known I. cengialtii, and a few years ago there appeared here a fine white form of the dwarf pallida of the eastern coast of the Adriatic, which promises to prove an admirable garden plant.

The Central European I. aphylla has also given me a white form, though in this case it is hardly a pure albino.

The well-known I. florentina is obviously nothing but a quasi-albino form of a purple germanica. I have obtained from the neighbourhood of Florence a slender, dark, black-purple germanica which closely resembles florentina in its habit, and, moreover, it is not at all unusual to find streaks or blotches of purple to appear in the flowers of florentina.

There is also to be obtained a so-called germanica alba, which is different from florentina and is the albino of some other of the numerous forms of germanica. I have also another form which I found in a roadside garden on the way up from Mattinghe to the top of Monte Maggiore, above Abbazia, in Istria. This has larger flowers than those of florentina and a white and not a yellow beard. In shape it recalls germanica atropurpurea, and may be an albino sport of that variety.

These various forms are sufficiently puzzling, but when we come to the various white Irises of the North-west Frontier of India our difficulties are vastly increased. It is these Irises especially which will not succeed after more than one or two seasons here, and I can only give M. Denis' experience of plants which have succeeded with him though they have failed with me. I. kashmiriana appears to be the white counterpart of a pale blue-purple Iris which is occasionally sent home from the neighbourhood of Srinagar, but which must not be confused with the Kharpot form of germanica. The latter has become naturalised there and is far more common, because more vigorous.

I. kashmiriana is distinguished from the white Irises already mentioned by its long, narrow spathes, which remain green till the flower has faded. This same character appears in I. Bartonii, which I took to be only a form of kashmiriana, but which M. Denis informs me comes true from seed. It is a smaller plant than I. kashmiriana, and its flowers are of a yellowish white, sometimes veined or suffused with purple. It is remarkable in having a number of long hairs on the inner side of the haft of the standards, whereas in kashmiriana there are only three or four short hairs. The original plants of Bartonii came from Kandahar, and M. Denis tells me that others which I received from Quetta and Abbottabad are slightly different forms and that all three reproduce themselves approximately true from seeds when self-fertilised, and remain distinct from I. kashmiriana.

In this connection it should be remembered that the real I. kashmiriana is seldom in cultivation in England. The forms obtainable under the name of "Shelford variety" or "Miss Willmott" are, as Foster himself told me, of doubtful parentage, and M. Denis finds that he obtains from them forms that are obviously akin not to kashmiriana but to mesopotamica.—*W. R. Dykes, Charterhouse, Godalming.*

be that of Sir Francis Younghusband, I wrote to him recently, and he was good enough to inform me that he knew nothing of the plant or its reputed discoverers. Sir David Prain, who was with the expedition, also feels sure no such Blackberry was found.

The Himalayan origin is therefore extremely doubtful, to say the least. When in Germany in the autumn of 1912 I was impressed with a very fruitful Blackberry called Theodore Reimers, and had plants sent to me the following winter. After several years of comparison I find it identical with the so-called "Himalaya," and have no doubt that this fruit found its way to America and there underwent the rechristening which often follows migrations.

Theodore Reimers is figured in the *Pomologische Monatshefte*, 1904, p. 49. It seems that seeds were raised from a plant found in a neighbour's garden by Garteninspector Theodore Reimers in 1889, and one of these produced the berry under consideration. All the evidence, therefore, points to the fact that it is descended from a European species of Rubus, as is indeed suggested by its appearance.—*E. I. Bunyard.*

APPLE JAMES LAWSON

THE new Apple named James Lawson, illustrated in fig. 81, is a cross between Cellini and

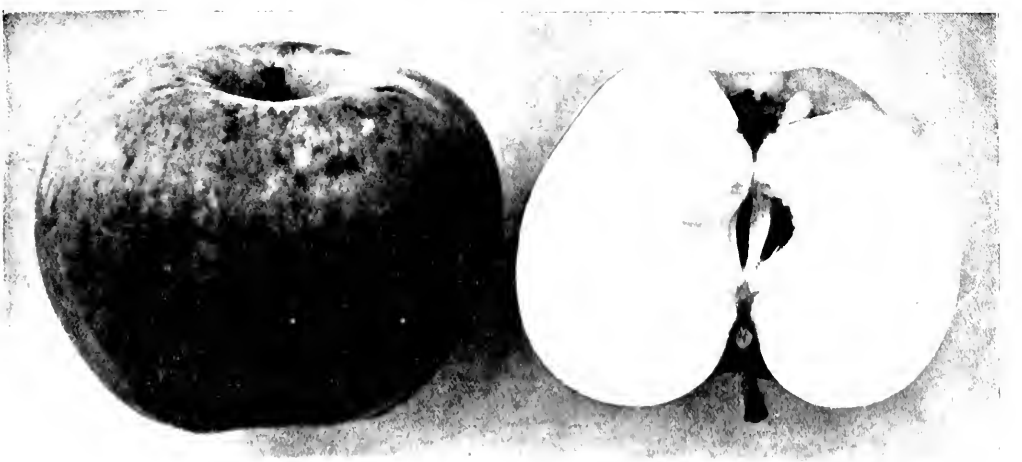

FIG. 81.—APPLE JAMES LAWSON.

FRUIT RECISTER.

THE HIMALAYAN BERRY.

THIS remarkable prickle Blackberry has been grown in this country for some years, and though the fruits are lacking in flavour it is without doubt a very remarkable addition to the list of trailing Rubi.

I have been trying for some years to get definite information as to its origin, and feel pretty certain that its source is European and not Indian.

Mr. Alfred Mitting, an American nurseryman, who specialises in these berries, gives the following historical particulars:—

"Unknown to the rest of the world, it had been growing for centuries in the Himalaya Mountains, when a British military expedition went north from India into Persia and Thibet, found it and brought back some plants. A Seattle firm brought the first plants into the United States in 1905, and since then Himalaya has been developed and tested until we know that for many purposes it is so altogether different and new and good that it is an invaluable addition to the fruits American farmers can grow."

I think that the expedition referred to would be that of Grossheim and resembles both parents in appearance. The skin is yellow, streaked with red. The flesh is juicy, firm and of good flavour. It is a dessert variety, ready for use in September. It received the R.H.S. Award of Merit on September 24, 1918, after trees in fruit had been inspected by members of the R.H.S. Fruit Committee in Messrs. H. Cannell and Sons' nursery at Eynsford, Kent. The fruits are illustrated natural size.

ON INCREASED FOOD PRODUCTION.

CLOSE PLANTING OF POTATOS.

WHILE dealing with the value of phosphate manuring for Potatos, Mr. Taylor (p. 169) stated that the experiment showed the folly of planting too closely. This is true in many respects, but not always, because the nature of the soil has to be taken into consideration. Last March I bastard trenched some grass land for Potatos, and the top soil varied from 3 inches to 8 inches in depth, with a subsoil of solid gravel. The soil itself is very sandy, and during the fine weather of March last it looked like so much dry sand or dust after being turned up for

a day or two. I concluded it would be useless to allow more space for Potatos than 2 feet by 1 foot. I planted the poorest part of the ground with Arran Chief, King Edward VII., and Up-to-Date. The first named grew 7 feet high in a garden the previous year, and the haulm had to be staked. This year, in the sandy soil, it did not exceed 12-15 inches in height. Up-to-Date made a second growth and continued green till the middle of October. Neither of the varieties was at any time crowded, and the top growth of Arran Chief never met over the furrows, except at one end, where the soil was deeper. Up-to-Date gave the heaviest crop, followed by Arran Chief, and most of the tubers were ware and seed size. I merely make these statements to show that the character of the soil must be taken into consideration before determining the width apart at which to plant. I have seen some of Mr. Taylor's cultures, and know that he is nothing if not thorough, and he is successful, too. In a trial of Potatos at Wisley last year the heaviest weight per rod was dug from Arran Chief, planted at 2 feet by 1 foot. The heaviest weight per root of the same variety was from tubers planted 30-36 inches × 16 inches. *J. F.*

POTATO YIELDS.

THE following results of ten varieties of Potatos grown alongside and treated identically, after Wheat, with a catch-crop of Clover ploughed in on sandy loam soil, may be of interest to readers. The cultivation was on a farming scale and not carried out under gardening conditions. Although the yields may not be as much as those to be expected from garden cultivation, the comparisons between the various varieties are nevertheless of interest:—

	Tons per acre
The Ally (Scotch seed)	15
Great Scott	15
King Edward	14½
Kerr's Pink (Scotch seed)	13
Arran Chief	12½
Ninetyfold	11½
British Queen	10
Up-to-Date	10
Dargill Gem (Scotch seed)	9½
Iron Duke (Scotch seed)	9

The sets were planted on April 23 and 25, with a good dressing of dung in the drills and 2 cwts. of sulphate of ammonia per acre. As the land is required for Wheat this autumn the Potatos were lifted early in September, before the tops had thoroughly died down, with the exception of Ninetyfold, which was lifted in a ripe condition on August 5, and British Queen in an almost ripe condition on August 10. All the crops were grown from Scotch seed once removed, except the four duly marked new Scotch seed.

In manurial tests carried out with the variety Great Scott the omission of sulphate of ammonia caused the tops to be lighter in colour, and the plants ripened rather earlier, and the yield was smaller to the extent of over one ton per acre. On the contrary, a dressing of 3 cwts. per acre of sulphate of potash 95 per cent. raised the yield over 3 tons per acre, but the tops showed no appreciable difference during the growing season. *T. E. Milne.*

AUSTRALASIA.

EUROPEAN TREES IN TASMANIA.

EVEN some Tasmanians who have been to England have a theory that European trees do better here than at home, but I think them wrong. Northern trees in the South of Tasmania are disappointing to me, if only they would thrive as well, and were as handsome and as introduced weeds, this would be a better looking place. Excluding fruit trees, generally speaking, they are not abundant. Beyond Pinus (usually *P. insignis*) round homesteads, Willows by creeks, a few Oaks and Poplars, and old Thorn hedges (almost invariably neglected), there is little more to catalogue, and a particularly grievous fact is that I have not yet seen a Beech tree worthy of the name. Nor does exotic tree growth in general seem to me anything exceptional; but, of course, we have only arboreal tree babies here, for what is 100 years in the life of an Oak? In the North things are rather better. In particular I have a good word to say for exotic trees generously planted in the celebrated Launceston gorge. Quite by accident I got to the place of a man as keenly interested in, and as wise about, exotic trees as anybody in the island. He must be thought a crank, because the rows nearest the road in his orchard form an arboretum, and few cultivators here soar beyond the strictly utilitarian. Also he has more than one modest exotic plantation, and has planted trees so extensively as to have thirty or so kinds of Oak, to example. He informed me that deep-rooting trees do well with him, but shallow-rooting ones are disappointing. And those that thrive, really do thrive. He showed me an Oak shoot 8ft. or 9ft. in length, while young Pines had made a similar annual growth. I should be grateful to any reader who would send me acorns of either *Quercus australiana*, *Q. coccinea*, *Q. Farnetto*, or *Q. pubescens* to gladden the heart of my friend. They are unobtainable in Australia. A tree which usually does as well as any here is the London Plane. Commercially, but only where there is a great depth of rich soil, there should be money in Walnuts in Tasmania. They thrive amazingly, and the nuts fetch high prices. The Spanish Chestnut is almost unknown, nor have I noticed large Horse Chestnuts. A tree which grows to an amazing size is the Mulberry. I have seen specimens far surpassing the largest known to me at home. *I. Garnett, Cambridge, Tasmania.*

SHODDY AS MANURE.

ONE of the fruit grower's greatest difficulties is to obtain enough farmyard or stable manure. It is possible to buy stable manure from London or other cities; but this is very dear and not of great value. In a crop of Potatos grown this year one could plainly see which part of the field was dressed with local manure and which with London dung, the former giving the heavier yield. Were it not that organic manure is essential on my light land, I doubt if London manure would be worth its price. The last consignment cost 5s. 6d. per ton on rail in London, and carriage brought it up to 9s. 3d. at the local station. By the time it has been carted home it costs between 11s. and 12s. per ton, and added to this is the heavy item of spreading.

This autumn I have, for the first time, bought several trucks of wool shoddy. In normal times this is considerably cheaper than dung, and, even under present conditions, it has the advantage. It is selling now at 12s. 6d. per unit of ammonia per ton delivered at the local station. Root growers, who use it largely, consider that two tons per acre of shoddy containing 6 per cent. of ammonia are equal to 20 to 24 tons of London manure; and I find that the former dressing costs about £7 15s. on the farm, as compared with at least £11 10s. for 20 tons of London dung. Then there is the labour of spreading, which is much lighter in the case of shoddy. If the shoddy is dry there is little difficulty in distributing two tons over an acre, but it is almost impossible with a wet sample, which is naturally much less bulky. My figures are probably hardly fair to dung, which is an all-round plant food, whereas shoddy supplies only nitrogen and organic matter. I am, however, pleased with the appearance of the shoddy dressing, because it promises to supply plenty of organic material of a lasting character, and that is what the soil needs. *Market Grower.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Asparagus.—The forcing of Asparagus is very easy, and a supply of succulent stems may be had in December and January if crowns are introduced into gentle warmth. A hot bed made of leaves and manure is preferable to forcing by means of hot-water pipes, as the fermenting materials will provide a moist atmosphere. A bed of Oak or Beech leaves about 4 feet in depth will provide a steady bottom heat for two or three months, and may be used successfully for three or four batches of crowns. Brick pits are the best structures in which to form the hot-bed; failing these, frames may be set on a mild hot-bed about 4 feet high. When the heat of either kind of bed has declined to 80° cover the bed with about 4 inches of light soil, but the roots should not be placed in position until it is seen that the heat of fermentation is not likely to exceed 80°. The requisite number of roots should be carefully lifted and as little exposed to cold, drying winds as possible. Place them closely together on the surface of the bed and cover them with at least 3 inches of fine, light soil. If the latter is moist little or no water will be needed, but, as a rule, the roots are better for being lightly moistened with tepid water. At no time should the roots suffer for want of moisture, or the quality of the shoots will be impaired. If high temperatures are guarded against there will be no necessity to admit much air; the temperature should be kept as near 60° as possible.

Shallots. Examine these bulbs carefully during the present month, and pick out any that are diseased or show the least signs of decay. To keep well the bulbs must be stored thinly in a cool place.

Parsley. See that Parsley in frames is well ventilated during fine weather, the soil stirred frequently between the rows, and all decayed leaves removed. Surplus plants in boxes may still be transplanted in frames to provide leaves for use in spring.

Autumn-Sown Onions. Hoe the soil between the rows of seedling Onions once or twice during fine, mild weather, but on no account make the ground too loose or encourage the plants to grow too quickly. In damp weather hand weeding is the best.

Gas Lime. The present is a suitable time to apply gas lime at the rate of four or five bushels to each ten-rod plot, spreading it evenly over the surface. After lying exposed until next spring or early summer, according to the amount used, the lime may be dug in and the ground cropped.

Potatos. Examine seed Potatos and remove any diseased tubers. They must be kept safe from frost, and paper mats or other suitable material should be kept in readiness for use in times of severe frosts.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Richardia africana (Calla). — Some of the strongest plants of the common Arum may be placed into warmth with a view to having them in flower by Christmas. The roots should be given liquid manure at every alternate watering, as Richardias are gross feeders when in active growth. The rest of the batch should be kept in a cool house, using fire-heat only to keep out severe frost. Fumigate the house at fortnightly intervals to destroy aphis.

Early-flowering Gladioli. Early flowers of Gladioli are always most useful for purposes of cut blooms. The corms should be potted as soon as they arrive from the seedsman, as it is important that they have plenty of time to become well rooted before attempting to force them into flower. Place them in 6-inch pots filled with a fairly rich compost, and plunge the pots in a bed of ashes in a cold frame. When

the shoots have grown about an inch or two remove the pots from the ashes and place them near the glass in a cool house, where they should remain during the greater part of the winter. When top growth is well advanced, and the pots are full of roots, batches of the plants may be placed in a warmer house for forcing.

Bulbs in Pots. Examine all bulbs growing in pots and other receptacles at regular intervals. When they have made an inch or two of top growth the pots containing them should be taken from the bed of ashes and placed in a cool frame. During times of very severe frost cover the frames with mats, litter, or similar protective materials. Place batches of the early flowering kinds in the forcing house at intervals according to requirements. A constant watch must be kept for rats and mice, which are capable of doing great damage to bulbs in a short time. Mice are easily dealt with by trapping. Rats may be poisoned, and this should be done by an experienced person.

Palms.—During very wet weather some of the outdoor stuff may be employed in cleaning Palms. Scale insects are the worst enemies of the Palm, and bad infestations are very difficult to eradicate. If the leaves are kept moistened with an insecticide the removal of the insects will be easier. Syringing the whole of the plants thoroughly with soluble paraffin at intervals of a week or ten days is the best way of keeping Palms clear of insect pests.

Euphorbia pulcherrima (Poinsettia). The bracts of Poinsettias will keep fresh for several weeks after they have fully developed provided the plants are grown in suitable conditions. Keep the atmosphere of the house quite dry and the roots on the dry side. Admit air whenever outdoor conditions are favourable, and circulate a little warmth in the water pipes at all times. During times of dense fog keep the house closed.

THE ORCHID HOUSES.

By J. COUTTS, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Odontoglossum. Plants of O. crispum that are nearing the completion of their growth should be suspended or stood near to the roof glass in the cooler part of the Cattleya or intermediate house. Reduce the supply of water at the roots gradually until after the new pseudo-bulbs are thoroughly developed, moisture should be withheld for longer periods, affording only sufficient to prevent the pseudo-bulbs from shrivelling. This treatment should be continued through the winter, and until flower spikes are seen to be pushing from the centre of the young growths. O. grande, O. Insleayi, and O. Schlieperianum grow satisfactorily during the summer months in a cool house, but now they should be grown near the roof glass in a house having an intermediate temperature. Plants of O. Edwardii Skinneri and O. luteopurpureum are forming roots at the base of the young growths, and any in need of fresh rooting material should be given attention. A compost consisting of Osmunda fibre or M fibre cut up rather roughly, with a liberal addition of crushed crocks, will be found suitable for these Orchids.

Zygopetalum and Allied Genera. The partially developed pseudo-bulbs of Zygopetalum Mackayi are sending out flower spikes, and from now onwards until the flowering season is over, extra care must be taken in watering the roots, for an excess of moisture may cause the leaves to become spotted. Water should only be afforded when the compost is dry, when sufficient should be given to soak the materials thoroughly. Plants of Z. crinitum, Z. Perrenoudii, Z. Prothesianum, and others of that class, also Zygo-Colax Wyganianus and Z. C. Charlesworthii, are in full growth, and should be afforded liberal supplies of water at the roots. All these plants thrive best in a moist, shady position in the cooler part of the intermediate house. Z. rostratum and Z. Boehlingianum are both growing freely, and should occupy a shady position in the warmest house. The surface moss should be sprinkled frequently in order to keep it green and healthy. Plants of the Bollensea section, such as B. coelestis, Pescatorea Lehmannii, P. Dayana, Chondrorhyncha lindenata and C. Chesterton are forming fresh roots, and specimens that require fresh rooting materials should be attended to in that respect. Zygopetalum maxillare and Z. Gautieri may, where necessary, be given more rooting space. Use a compost consisting of equal portions of Osmunda fibre or M fibre and Sphagnum moss cut in rather short particles, with a liberal addition of crushed crocks. These Orchids have a rambling habit, and are not suitable for growing in pots or pans; they do best fixed to a portion of the stem of a Tree Fern. If necessary, the rooting space may be extended by wiring another piece of stem on the top of the old block. The roots should be kept moist at all times. The plants thrive best in a moist shady position in the warmest part of the intermediate house.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

Mid-Season Vines. Successional houses in which the bunches of Grapes are still hanging should now be cleared and every opportunity taken to assist in the work of pruning the Vines and cleansing the houses before the end of the year. The instructions given in the issue of October 12 for early Vines may be followed with successional houses. The removal of the berries from over-crowded bunches, and permitting a moderate application of water to the border, are two important points of remembrance. Top-dressing cannot be performed too quickly, and where the Vines have the run of internal and external borders the renovation of the latter should be carried out at this season. If the Vines are in a healthy condition a top-dressing, 2 or 3 inches in thickness of a suitable compost and subsoil, after removing all the old mulchings and exhausted soil down to the young roots.

Late Vineries. Unremitting attention should be given to the Vines in which Grapes are hanging in order to keep the berries plump. This is the most important factor in the keeping qualities of the Vines, and the chief cause of the shanking of the berries. Maintain a dry, airy atmosphere, slightly on the warm side, by allowing a gentle circulation of heat in the pipes until the leaves fall. A temperature ranging from 45° to 50° will keep the Grapes free from moisture, but any fluctuation below this will cause the berries to attract and hold moisture. Decay soon follows, and with frequent cutting out of decayed berries the bunches are spoiled. If such cases it is advisable to cut the bunches and place them in bottles containing water in the Grape room. Above all, avoid keeping the house damp for a lengthened period.

Tomatos. Plants in 8 or 9 inch pots for planting early next spring, should be placed near the roof glass. A temperature of 55° to 60° is necessary to keep the plants in a healthy condition. If this cannot be maintained through the winter it is advisable to discard the plants and reserve the fruit for an early start in the New Year. Even plants which are now ripening their fruits require a similar temperature. Water the roots very carefully, maintain a fairly dry atmosphere, and syringe only on the occasion of bright, favourable weather.

THE HARDY FRUIT GARDEN.

By G. DAY HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Apples and Pears on Grass. Assuming that the annual mulch of soil around the trees has been kept two feet clear, it is advisable to extend the ring as the trees increase in size. When doing this scatter the soil around the stems and top-dress the roots with rather rich, fresh loam or well-rotted manure, allowing, of course, for the cropping proclivities of the variety in question. If the trees be of full age it will repay to remove some of the surface soil and replace it with fresh compost liberally mixed with manure. This will encourage the development of roots near to the surface. In the case of large Plum trees that have borne freely in the past two seasons a good dressing of fresh loam mixed with lime rubble would prove as well of strawberry. These trees also would have an area of cultivated ground around the stems as in this way more generous treatment can be given them.

Planting Trees. The work of planting fruit trees should proceed as quickly as possible, for while the weather stays very open and the ground is nearly every instance in good working condition there is no excuse for delay. A good deal of very short work and a proper concentration on this most important item will leave other matters for a time. If the trees do not yet to hand for everything be done in the way of preparation, so that they can be planted on arrival. Do not stop for any planting under foot of the roots. Have good soil or compost for covering the roots where the ordinary soil is not good enough for the purpose. Leave the mulching, if such be deemed advisable, until all the planting is finished, but give the watering to settle the soil.

Renewal and Extension. After the good results of last season's increase of fruit tree cultivation, there is every reason for the crops this year to be even above the average, and the value of fruit has been more than ever appreciated, not only as a luxury, but for its dietetic value. Let no available space on walls or fences be left bare. I have lately seen boundary fences covered with Loganberries (American), or Parsley Aphis. This was accomplished by keeping the canes pointed as a screen some 3 feet or so away from the fence. Last spring I advised the planting of standard trees in shrubberies, and I now repeat it. Trees on clean stems, as standards, are to be had, and often times these are better when rather tall, and just what is needed for the purpose. These may include Apples, Pears, Plums, and Damsons, even Quinces on most soils.

Painting Ironwork. Any painting of ironwork that may be needed should be done now rather than in the spring, such work must not be neglected, and the best material to use is oxide of iron paint, apply two coats after cleaning off any rust.

THE FLOWER GARDEN.

By G. H. P. THOMPSON, Gardener to the Earl of HARDWICKE, Tyringham, East Lotham.

Ranunculus and Anemone. These bulbous plants may be planted now for an early display of bloom next year. Anemones are well known, but Ranunculi are now seldom seen in gardens though at one time the quaint Turban and Persian groups were invariably grown in beds. The easiest strain to grow is the French, a free flowering and pretty group, but innocent of the high hue and doubling of the others. In planting, some care is required not to break the "claws." Plant about 3 inches deep, not more, and about 4 inches apart. A well worked, deep soil is desirable, with plenty of rotted manure incorporated. After planting nothing further will be needed by them till February, when the surface soil should be stirred and a dressing of soot dusted among the growing plants.

Storing Roots. Begonias will be quite ready to store after removing all the current year's growth from the tubers. Keep as much soil as possible on the tubers and store them in heaps in a frost proof building. Gladioli will also be in a fit condition for cleaning and the removal of old tobacco. At the same time all the little corms which cluster about the old ones should be preserved for increasing the stock. Our stock is dried and wintered in a cool Peach house, the corms lying on the border, a method I think to be preferred to placing them where they become very dry indeed, there are so many that a somewhat rough and ready way of keeping them has to suffice.

Rubus phoenicolasius. The winter beauty of this common shrub is not recognised to the extent it ought to be. Now that the leaves have fallen all the old shoots should be cut out, leaving only those of the current year. On sunny days the rich brown of these shoots is very effective, and it may be added the effect is heightened when groups instead of single plants are seen. Other Rubi may be treated similarly, also the green barked Leycesteria formosa and Pentantinus nepalensis, Corchorus japonicus, Deutzias. Willows should be left till March and then be cut hard back; if dwarfs, cut just below the surface, and, if standards, always allow for a few fresh strong shoots to start well back at the base. It is strange that so little is made of shrubs with beautiful bark.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publishers.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 51°.

ACTUAL TEMPERATURE:—*Gardeners' Chronicle* Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, November 20, 10 a.m. Bar. 30·4, temp. 41°. Foggy.

Ploughed-up Grass Land.

The experience of the past few years in ploughing or digging up and planting grass land has taught that not all crops are equally suitable for planting in the first year.

Broadly speaking, it is probable that the Potato has proved itself one of the best crops to plant—provided that the sets are encouraged to grow away from wireworm by a dressing of sulphate of ammonia at planting time. But it is pretty certain that there are some other crops which do even better than the Potato. First in order is Mustard, although this is a crop the extension of which is not wanted at the present time. Next to Mustard, as we are informed by one of our leading market gardeners, come Onions. Presumably this applies only to soils not too light in texture, but even so, it is information well worth noting, for in view of the great importance of the Onion as a food crop, and of the fact that we grow far fewer Onions than we consume, it is much to be desired that more ground should be put under this crop in the coming year. With shipping rates likely to rule high, the foreign-grown Onion cannot compete naturally with the home-grown article, and therefore it should be the duty of the State to encourage, and of the community of horticulturists to grow as many Onions as possible. Every ton raised at home, even after giving a proper return to the grower, means a saving of the pocket of the public and a certain measure of relief to shipping. There can be no doubt but that transplanted Onions, if grown on suitable ground, give good prospects of a large crop, and the fact that this vegetable does well in newly turned up grass land should be noted by those who have the supply of labour requisite for the cultivation of this crop. Nor is there any reason why the prejudice against red Onions should be maintained; in fact, one of the best of all croppers and a good keeper, is Weathersfield Red, which variety has the further merit that it does well on soils not too kindly disposed to the white-fleshed kinds. Nurserymen who are doing so much for food production have already in the past two years cultivated considerable breadths of Onions, generally with marked success, and it uncertainty with respect to prices did not act as a deterrent they would probably do more in the coming year. But it has to be remembered that the Onion is in any case uncertain in its yielding capacity, for it is very prone to the attacks of insect pests and fungous diseases.

Yet another crop which the experienced claim as suitable for cultivation on recently turned-up grass land is the Pea. Besides field Peas, those of the ordinary kind, as for example, Little Marvel, are said to do well and to escape damage from wireworm. This is probably due to the fact that Peas very readily, and indeed normally, in the course of their growth throw out adventitious roots, which stand a good chance of persisting even though the main root of the seedling may be attacked by soil pests.

Lastly, it may be mentioned that transplanted Tomatos take very kindly to ground in which the turf has quite recently been turned in, and here again is a crop of which considerably more than is now produced could be utilised, although, of course, the precarious nature of the English summer attaches a certain measure of risk to Tomato growing in the open.

The Gardeners' Royal Benevolent Institution.—We heartily commend to the notice and practical sympathy of our readers the following appeal, issued by Sir HARRY J. VEITCH on behalf of the funds of the Gardeners' Royal Benevolent Institution: "As treasurer of this institution for more than 50 years, and therefore thoroughly acquainted with its excellent work, I plead most earnestly for financial help in this time of great stress when the need is so urgent. The absence of the usual festival dinner in aid of the funds, held without intermission since 1845 until the present terrible war broke out, has sadly lessened our income, necessitating drawing upon an emergency fund, which is now almost exhausted. In these circumstances a very warm friend of the institution, who wishes to remain anonymous, has most generously offered £250 this year, and to continue the amount annually until one year after the cessation of the war, provided three other similar sums or lesser amounts amounting in the aggregate to £750 are obtained, or to give £500 on the same conditions if £1,500 is raised. Towards this the Committee have already received and gratefully acknowledge more than £250. I therefore appeal to the generosity of your readers in order that the Committee may take as full advantage as possible of this very generous offer. HARRY J. VEITCH."

The "Gardeners' Chronicle" in Mesopotamia.—Private A. C. DAVIS writes: "Just a line to let you know that I am getting the *Gardeners' Chronicle* safely each time we receive a mail. I thank you for the prompt and regular manner in which you despatch it to me. As in pre-war days, it is read with great interest by myself and others who in civilian life are gardeners. We are glad to have the old paper out here with us, as it helps to keep us in touch with our work while we are far away in Mesopotamia. When we return we shall be very keen and eager for work, and no doubt the head gardeners of England will be glad to see us again. The same address will still find me. I wish the *Chronicle* every success."

Ghent.—The evacuation of Ghent by the Germans and its reoccupation by Belgian and British troops have given rise to wonderful scenes of rejoicing in this great horticultural centre, and many British horticulturists will join with their Belgian confreres in thankfulness that the peaceful pursuit of commercial gardening may once more be carried on in this city of nurseries. Had there been no war the present year would have witnessed the holding of one of the great Ghent Quinquennial Horticultural Exhibitions for which the city is famed throughout the world. We hope the day is not far distant when those interested in the "gentle art of gardening" may be permitted to meet once again at the Floralies to congratulate the gardeners of Flanders upon their stand for liberty, their liberation from bondage, and their wonderful horticultural productions.

The Corn, Pulse, and Hay Crops. — The yield per acre of all the corn crops in England and Wales this year is above the average, and with the single exception of the small area of Beans, the total production is also greater; while all are better, whether judged by the yield from an acre or by total production, than in 1917. The yield of Wheat is estimated at 33 bushels per acre (2 bushels above the average), and the total production, upon the greatly increased acreage, amounts to 10,534,000 quarters, which is the largest quantity harvested since estimates were first officially collected in 1885, and exceeds last year's total by 3¼ million quarters. A certain proportion of the Wheat has been damaged, especially in the northern districts and in Wales, but the condition of the bulk is satisfactory. Barley has yielded 32 2/5 bushels per acre, or half a bushel more than the average; the total production of over 6 million quarters is the largest since 1914. The production of Oats is almost 2 million quarters more than the previous highest on record (1907), and amounts to 14,336,000 quarters; the yield of 41¼ bushels per acre is the best since 1910. Mixed or dredge corn, distinguished for the first time, produced an additional 620,000 quarters from 139,000 acres. The damage to Barley and Oats has been considerably more serious and widespread than in the case of Wheat. Beans have given 29 2/5 bushels to the acre, while Peas, with 27½ bushels, show the best return of the last ten years. Taking all the five corn crops together the gross production in England and Wales was no less than 81 million quarters, or quite 35 per cent. more than in 1917. The yields of seeds' hay (Clover, Sainfoin, and grasses under rotation) is practically equal to the average, viz., just 29 cwts. per acre; but that from the permanent grass (21 4/5 cwts.) is 4/5 of a cwt. below the average. Owing to the increased production of corn, the total amount, viz., almost 2,100,000 tons of seeds' and nearly 4,700,000 tons of meadow hay, is less than that taken last year, in spite of the better yield per acre. The total production of hay of both kinds amounts to 6,785,000 tons, or fully three-fourths of a million tons short of last year's total, and nearly 1,100,000 tons less than the average from the much larger area of the ten years 1908-17.

A Gardener Candidate for Parliament.—The list of parliamentary candidates for the East Hertfordshire division includes the name of Mr. CYRIL HARDING, Secretary of the British Gardeners' Association. Mr. HARDING is standing as a Labour candidate, and his opponents are Mr. PEMBERTON BILLING (Independent) and Mr. E. B. BARNARD (Coalition).

Distribution of the Potato Crop.—The scheme adopted by the Ministry of Food for disposing of this year's Potato crop is as follows: Prices to producers will vary in different areas; prices to consumers for the same grade of Potato will be uniform throughout England and Wales. Potatos will be supplied to retailers at a uniform price, fixed conditionally, at £9 per ton, Grade I., £7 per ton, Grade II., the price being reckoned to retailer's nearest railway station. Growers selling to wholesale dealers will be entitled to receive assessed price within 14 days, and if they do not do so they are entitled to apply to Potato Control Committee (in a de-

hert zone) or Zonal Committee (in a surplus zone) of their zone, as the case may be. Wholesalers are entitled to charge a commission of 7s. 6d. per ton; they must account to the Ministry of Food for the difference between the price paid to growers and price obtained from retailers after deducting commission (at rate of 7s. 6d. per ton) and necessary charges. As a general rule, only one wholesaler's commission may be charged in respect of any lot of Potatos, and if they pass through the hands of more wholesalers than one, commission must be shared. Special cases will, however, be considered, and an additional collecting dealer's commission not exceeding 3s 6d per ton may, upon application for the necessary licence, be allowed in cases of proved necessity. Both retailer's buying price and wholesaler's commission are subject to revision when further information as to actual costs has been obtained. No person may deal in Potatos by wholesale unless he is registered by the Ministry of Food, or by retail unless registered by the Food Control Committee of his district. Wholesale dealers will not be allowed to sell Potatos to any person other than registered retailers or wholesalers, unless they hold a licence to do so from the Food Commissioner of their area. Such licences will be granted to wholesale dealers who can show that they have a regular trade in supplying Potatos to caterers, fish-friers, institutions, or other large customers, and will be limited to sales of Potatos to such large customers. Subject to restrictions imposed by the Potato Control Committee or the Zonal Committee, growers will be permitted to sell Potatos to any registered wholesale dealer in their zone, but may not sell to anyone else except under licence to be obtained from the Food Commissioner of their district. Such wholesale licences will be made at the appropriate price for the class of sale authorised, but growers of more than 5 acres will be required as a condition of obtaining such licences to grow areas so adjusted as to secure that their net profits are equivalent to the greater price fixed for their district together with the extra cost required to cover cost of additional cartage and a maximum of 2s. 6d. per ton. Growers of less than 5 acres will not as a rule be required to grow any, but if they wish to be registered to sell without licence (Grade II. Potatos) in the counties of Berks, Bucks, Herts, Oxford, Sussex, and Wiltshire they will be required to grow such acreage. Growers will not be allowed to sell under the Order Potatos to a merchant at a price of £5 10s. per ton, f.o.r. Unclassified Potatos for which a market cannot be found in the ordinary way will be taken over by the Ministry of Food at the fixed price of £5 per ton.

Government Grants to Agricultural Societies. The Joint Parliamentary Secretary to the Board of Agriculture (Sir R. Winfrey), in reply to a question asked in the House of Commons by Colonel Lamb Wilson, whether any grant of public money, and, if so, of what amount, is made, either by or on the recommendation of his Department, to the Agricultural Organisation Society or the Agricultural Wholesale Society, whether there is any connection, and if so, what, between those two bodies; and whether societies or individuals affiliated to the Agricultural Organisation Society receive any special treatment with respect to discount to goods purchased from the Agricultural Wholesale Society, stated that grants of public money to the Agricultural Organisation Society have been made since 1909-10. Those for the current financial year are £10,000 from the Treasury through the Food Production Department, £4,000 from the Small Holdings Account, and from the Development Fund a block grant of £5,000, together with a grant equal to four times the amount of the Society's income from contributions from affiliated farmers' societies during the current year, and a grant equal to the amount of the subscriptions received in the same period. The grants are all subject to Treasury sanction. No Government grant is made to the Agricultural Wholesale Society. That society is the central trading body of the agricultural co-operative movement, the Agricultural Organisation Society being a purely propagandist, organising, and advisory body. The Agricultural Wholesale Society was formed under the auspices of the Agricultural Organisation Society, and on its initiative, as an essential part of its work of organising co-operation, but there is, I am assured, no financial connection whatever between the two bodies. In reply to the third part of the question, I may say that, as the Agricultural Wholesale Society is an independent body receiving no grants whatever from the Government, it is free to make whatever terms it likes in regard to its trading. Colonel L. Wilson: Does the right hon. gentleman consider it quite fair to private firms who pay income tax that a Government subsidy should be given to societies working in opposition to them, and will he take into consideration that these societies, registered under the Friendly Societies Act, do not pay income tax as private firms do? Sir R. Winfrey: I said the subsidy of the Government was to the Agricultural Organisation Society, which is a purely propagandist society.

BEGONIA EVANSIANA.

The now popular genus Begonia was first made known to gardeners in this country by the introduction from China in 1804 of B. Evansiana. The first record of it is in Aiton's *Hortus Kewensis*, where it is named B. discolor, and is said to have been introduced by the Hon. Court of Directors of the East India Company. A good illustration of it was given in the *Botanical Magazine*, t. 1,473 (1812), and it is there described as a highly ornamental stove plant, easily propagated by cuttings, or by the bulbils produced in the axils of the leaves; also that it is in flower for most part of the summer. Although not a common plant in greenhouses today this Begonia still occupies a place among garden plants, and that it still deserves to be called highly ornamental was shown by a group of well grown plants of it in flower in Greenhouse No. 4 at Kew this autumn, where they were an attraction for about two months. The plants (see fig. 32) were about 18 inches high, well branched, the leaves green above, the veins on the underside crimson, and the flowers rose-pink. The rootstock is tuberous and perennial, the stems knotted and annual, and the axillary bulbils fall off and start growing in spring in the ashes under the stage in a cold house, where the plants are wintered dry. No plant is easier to grow, and none less likely to be lost. At Kew it is treated as a greenhouse plant, and is quite happy. If a cross could be raised between this and the summer flowering tuberous Begonias the hybrid would have a distinct value. B. Evansiana is the most ornamental of the few species of the genus found in China.

FIG. 32.—BEGONIA EVANSIANA: FLOWERS PINK.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

"Rogues" among Potatos.—Mr. Sutton's last letter refers to an earlier test of what I thought might be a "sport," and says it was identified as White Beauty of Hebron. I may state that Mr. Sutton wrote me on December 4, 1905. The Potato proved to be White Beauty of Hebron, or Puritan. The next year I grew the three side by side; their foliage was much alike, but the tubers of the tested one took such extraordinary shapes as to baffle comparison. Since then I have grown rows of Potatos from seeds, bought of Messrs. Webb and Sons, and some of the seedlings grew in the same fantastic way. Singularly enough, nearly all the conditions Mr. Sutton names are reasonably complied with in the Potato "sport" I still possess. For instance, in 1904 my garden was made in land which had been, for many generations, an open freemen's common; in 1905 the "sport" appeared, and I am satisfied the other conditions are fairly well met. However, I have a number of the tubers now, in a box, to sprout for next year's planting, and I shall be quite willing to submit them to any further test, should such be desired. The tests were to ascertain whether it was a "sport" or not, and at my special request they were kindly continued a year longer than Messrs. Sutton desired, with this object in view; it was not for commercial value. On referring to the articles in your back volumes, and which Darwin named, I am able to say that, as I had confidently expected, every sentence of Darwin is fully borne out in the plain sense in which he wrote. He says: "A single bud or eye sometimes varies and produces a new variety, or occasionally—and this is a much more remarkable circumstance—all the eyes in a tuber vary in the same manner and at the same time, so that the whole tuber assumes a new character." Mr. Sutton's view is entirely the opposite of this. As to Kemp's Potato, the reference (1841) is: "A plant was dug up having two white tubers, the colour of the variety, and two others, which were red. Considering this to be something out of the common way, a gentleman took the plant, with the tubers still attached to it, to Mr. John Taylor, a highly respectable nurseryman at Preston. Mr. Taylor wisely preserved them and planted them the following spring, when he found the produce was red, and not only were they of a different colour, but they were, on comparative trials, found to be more productive, and, if anything, superior in quality, to the variety from which they sprouted. This variety is now well known throughout the kingdom, I believe, under the name of Taylor's Perfected." *John Tuardley.*"

And yet Mr. Sutton maintains that Darwin referred "exclusively to colour variation." Also, when Darwin states, "It is an argument of the greatest weight that when varieties are produced by simple bud-variation, they frequently present new characters," I consider it plain, with such cases before him, he cannot mean change of colour only, and it would be well for growers to act upon the opinion of such an eminent authority. "Bud variation" is his term for gardeners' common word, "sport." As to the causes of "sports" in plants, we really know nothing; all we know is that they exist. As to eyes of Potatos being cut out and inserted in others, to which Mr. Sutton refers, Darwin says, Chap. XI., p. 421, of the same book the Potatos produced by graft-hybrids "were of all colours and shapes, some very ugly and some very handsome," and "some of these varieties have been found valuable and have been extensively propagated." There is much more of the same kind. The truth appears to be that some "sports" are, like the cross fertilisations of the flowers, inferior to their predecessors, some as good, and others better. Considering the great value of the Potato, of which the war has furnished such an object-lesson, truth should be taken advantage of by testing future "sports," not treating all as "rogues," to be destroyed. This was the purpose I had in view in initiating the present friendly correspondence. I welcome Mr. Taylor's letter as helping to give light on this object.—*S. Judson.*

American Blight. Mr. John Bates asks (p. 180) whether certain varieties of Apples are immune from this pest. It is to be hoped that there will be numerous replies to this question, for a reliable list of immune varieties would be valuable. Possibly none is absolutely immune, and it is quite likely that a variety that escapes in one district is badly attacked in another, but there is no doubt that the pest very much prefers some sorts. In my oldest orchard the trouble has spread seriously, particularly on Cox's Orange Pippin, Beauty of Bath, and Allington Pippin, but I find that it has missed Lord Grosvenor, Lane's Prince Albert, Royal Jubilee, Worcester Pearmain, Blenheim Pippin, and Gladstone. I do not remember to have seen it on Bramley's Seedling, except where this variety is used for top-grafting. When removing the wax from top-grafted trees this year I found American Blight on nearly every junction, though how the insects got under the wax is a mystery.—*Market Grower.*

Fasciation not Inherent. Mr. H. G. King's letter regarding a fasciated Vegetable Marrow in your issue of 12th ult., p. 147, is very interesting, but after having experimented on several heads of Wheat, of which the one illustrated in fig. 85 is an example, I fear that he will find the Marrows will revert to the ordinary type next year. I have saved the seed from several "double" Wheat heads similar to the one in the illustration, but in all cases the progeny reverted to the usual type, showing that fasciation is a physical and not an inherent property.—*T. E. Vida, Winscombe, Cross Lane, Latchford Without, near Warrington, Cheshire.*

FIG. 85.—EAR OF WHEAT HEAD.

Silver Leaf Disease. The Food Production Department and various correspondents in the *Gardeners' Chronicle* have recently called to draw the attention of fruit growers to the danger of Silver Leaf disease, which is increasing to an alarming extent, especially on Plum trees. I am however at a loss to know why the Food Production Department does not offer suggestions or methods of dealing with affected trees beyond cutting out the diseased wood. I am induced to ask with this Department's resources for scientific research that a cure for trees that are attacked by the cutting away of a branch once or twice check the disease, if the constitution of the tree is the direct cause of the trouble. I should like to know the cause of any tree that, apparently healthy on the surface, a few days afterwards show signs of disease, and I should like to know why Silver Leaf disease has the best known to exist before. Surely there is a reason for attacks of this. We read of the ravages of the Potato disease, which, after one of the crops had been destroyed, it was known that the following crop would be attacked, and I think it is time that the Food Production Department took up the matter. Mr. Hay, speaking at the meeting of fruit growers on the 13th inst., said that trees grown on their own roots were more liable to the disease than those grown on the Crab stock. I too think that trees grown on their own roots are not nearly so liable to the disease as those grown on the Crab stock, but I have had many trees grown on the latter conditions. My experience with Apple trees leads me to state that any other method of fruit production beyond grafting or budding gives poor results. I have two trees of Apple Mank's Codlin thirty years old growing on their own roots, and I would not like to increase the number. In Mr. Hayward's remarks on planting one would infer that he thinks the trouble may be owing to soil or wrong cultural conditions. I wonder what his views are in that respect, or does he agree with the oft-expressed notion that the spores of the disease are floating in the air ready to take advantage of any abrasion of the bark caused by careless pruning or other mistakes on the part of the grower, or by cattle?—*E. Molyneux.*

The Loss of the Clematis in Gardens (see p. 165).—Mr. Robinson deserves the thanks of all lovers of the Clematis for drawing attention to the wholesale destruction of those graceful plants by the folly of grafting. When I was a lad we layered the plants in 4-inch pots under glass, and hardened them off when they were well rooted. Since then I have planted many grafted plants, but had no success with them. I have grafted Muscat Grapes on to the Foster's Seedling, but who would graft Grape vines for sale? Even certain Roses do better on their own roots than cuttings.—*J. P.*

SOCIETIES.

ROYAL HORTICULTURAL.

NOVEMBER 19.—There was a very pleasing and interesting display at this November meeting, held at the London Scottish Drill Hall. The exhibition was by no means a large one, but it included Chrysanthemums, Orchids, fruits and vegetables, Ferns, winter-flowering Begonias, and bottled fruits and vegetables. These last were from the Food Production Department, and merited the Gold Medal awarded. A similar high award was made to the Ryecroft display of Chrysanthemums.

The Floral Committee awarded one gold and two other medals, one First-class Certificate, and two Awards of Merit. The Fruit and Vegetable Committee awarded three medals, including a gold one, and confirmed awards made to Brussels Sprouts at Wisley. The Orchid Committee granted two medals, one First-class Certificate and one Award of Merit. The Hall was very cold and the attendance poor. Mr. Godsall lectured on "The Care of the Soil" at 3 p.m.

Floral Committee.

Present: Messrs. H. B. May (in the chair), W. J. Bean, E. A. Bowles, S. Morris, John Green, Geo. Harrow, John Heal, W. Howe, J. Jennings, C. B. Fielder, J. F. McLeod, Thos. Stevenson, Chas. Dixon, John Dickson, E. F. Hazelton, W. P. Thomson, E. H. Jenkins, Chas. E. Pearson, and A. G. Jackman.

FIRST-CLASS CERTIFICATE.

Pyracantha Gibbsii.—A large branch of this handsome shrub was shown and generally admired. The branching is horizontal and the branchlets and twigs crowded with small scarlet fruits of a deeper shade than those of the popular *P. Crenulata*. The leaves are about 2½ to 3 inches long and half an inch wide, oblong-lanceolate and of a deep shining green colour. A flowering branch was illustrated in *Gard. Chron.*, December 3, 1904, p. 134. Shown from the Superintendent's Gardens, Wisley.

AWARDS OF MERIT.

CHRYSANTHEMUMS.

Lyric Reflection.—A bright yellow single variety of the largest size. There are two rows of large florets, and the form is first-class. A bold and effective flower.

Cornfield Glory.—A handsome late Japanese sort of the incurved style, described on p. 291, and shown in very good form. Both shown by Mr. Norman Davis.

The most brilliant exhibit was one of Chrysanthemums arranged by Mr. H. J. Jones, Lewisham, this occupying a table half the length of the hall and included nine large stands of blooms in a setting of specimen flowers and

small vases of decorative varieties. Outstanding varieties were Brilliant, a vivid crimson Japanese variety that is well named; Marshal Foch, a new and large pale yellow form; Sunset, an orange fawn decorative variety; Mr. D. Lloyd George, crimson; and such useful singles as Bronze Beauty, Golden Spray, Supreme, Buttercup, Peace, Cooper, and the big yellow Isobel Felton. Cultural Medal.

Among several new Chrysanthemums from Mr. NORMAN DAVIS his Enamelled Glory was a better form and colour than when it gained a First-class Certificate from the National Chrysanthemum Society (see p. 141). Messrs. GODFREY AND SON had a showy bronze sport from the sauge Molly Godfrey, and a very bright chestnut sport and good single named Reginald Godfrey. Bronze Banksian Medal.

Messrs. H. B. MAY AND SON exhibited Ferns, winter-flowering Begonias, and Cyclamens. Silver Flora Medal.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart., in the chair; Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), R. A. Rolfe, Arthur Dye, W. Bolton, R. Brooman-White, Chas. H. Curtis, Fred. Sander, C. J. Lucas, T. Armstrong, E. R. Ashton, Pantia Ralli, Frederick J. Hanbury, W. J. Kaye, and J. Wilson Potter.

AWARDS

FIRST-CLASS CERTIFICATE.

Sophro-Laelio-Cattleya Warscewiczoides × *S.-L.-C. aesculapius* var. *Olivia*.—*L.-C. Gottoiana* × *C. Schilleriana*, from C. J. Lucas, Esq., Wavertree Court, Heathfield, Sussex. Mr. Duncan's splendid hybrid the first flower of which was fully described in *Gard. Chron.*, November 2, 1918, p. 175. The plant was shown with a second bloom developed from the same inflorescence; the flower, which was inferior to the one described on p. 175, was of an intense vinous-purple tint, the fine ruby crimson with an orange-coloured base. It is one of the best of hybrids having Sophronitis grandiflora as one of its ancestors.

AWARD OF MERIT.

Laelio-Cattleya × *St. George var. Illawarra* × *Peetersii* × *L.-C.* × *St. Gothardi*, from Messrs. CHARLESWORTH AND CO. Has vivid bluish-lilac sepals and petals of dark rosy-mauve, with a golden flush; the lip crimson-purple with yellow lines at the base.

PRELIMINARY COMMENDATION.

Odontioda Morsiana × *Odontioda Bradshawiae* × *Odontioda Charlesworthii*, from Messrs. CHARLESWORTH AND CO. A desirable step towards producing Odontiodas equal in size and form to Odontoglossums, but with the characters inherited through Cochlioda Noezliana. The segments of the finely formed flower are almost covered with the clustered blotches of dull red-purple on the white ground tones.

× *Odontioglossum Memoria Crawshay* × *Hunnewellianum*, from Messrs. CHARLESWORTH AND CO. A grand flower with rich claret blotching on white ground, the colour extending through the segments and appearing bright-y on the reverse side.

CULTURAL COMMENDATION.

To Mr. J. COLLIER, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Surrey, for a fine plant of Cattleya Portia coerulea (Bowringiana violacea × labiata coerulea), with a spike of nine flowers, in which the pale blue tint of the parents is perpetuated.

OTHER EXHIBITS.

Sir JEREMIAH COLMAN, Bart., showed another plant from the batch of Brasso-Laelio-Cattleya Antoinette, the fine example of which, without much evidence of Brassavola, gained a First-class Certificate at the last meeting. The plant now shown offered distinct evidence of its Brasso-Laelia parent. This exhibition also showed the pretty yellow Cattleya Drapsiana Golden Glory (Mrs. Pitt × Dowiana aurea-Statterana).

R. WINDSOR RICKARDS, Esq., Tsé Priory, Monmouthshire, sent a pretty flower of the original form of Sophro-Laelio-Cattleya Isabella (C. Fabia × S.-L.-C. Marathon), with salmon-coloured sepals and petals, faintly shaded with apricot-yellow, and a ruby-purple lip with yellow lines from the base.

Mr. ALBERT FISHER, Winchmore Hill, showed Cypripedium Florence Fisher (Gracosa × insigne Rochdale Hall), resembling a small C. Rolfeae, the flower having a white ground and dark purple markings.

Messrs. CHARLESWORTH AND CO. were awarded a Silver-gilt Flora Medal for an extensive group of hybrid Cattleyas, Laelio-Cattleyas, Odonto Gossums, and Odontiodas. Remarkable among the home-raised seedlings was the handsome *O. crispum* var. *L. memoria* with large, well-formed flowers, evenly blotched with claret-red. The group was rendered specially interesting by the presence of a number of late species, including the scarlet *Habenaria Rochelenii*, Burgoyne's Medusae, *Bestopea senatia*, and Pescatorei's *Rossioglossum*. The rare *Disa Ithia* was there in handsome flowers equal to those of *D. grandiflora*, was added to the collection.

Messrs. ARMSTRONG AND BROWN, Orchidists, Tunbridge Wells, were awarded a Silver Flora Medal for a group of home-raised Cattleyas, Laelio-Cattleyas, and Odontoglossums, among which Odm. Ainsworth Orchidhurst 'variety Lambeauianum' crispum was a very fine flower, partaking largely of *O. crispum*; it is white with two irregular oblong reddish blotches in the middle of the petals. Some seedlings flowering for the first time showed good and distinct floral features. Forms of the white Cattleya Saturn and a rich crimson Odontiola Cooksonia were also included in this group.

Fruit and Vegetable Committee

Present: Messrs. Joseph Cheal, in the chair; G. P. Berry, E. Hobbs, H. Markham, F. Perkins, P. Ecckett, A. Allen, E. Beckett, Owen Thomas, E. A. Bunyard, W. Bates, A. Bullock, and the Rev. W. Wilks.

A splendid and educational exhibit of fruits and vegetables, with Mr. Vincent Banks in charge, gave some idea of the work done in this important branch of horticulture by the Food Production Department. Needless to say, Mr. Banks' corner is of the highest excellence, and no food product of vegetable seems to be beyond his skill to present in an attractive and appetising form. There were about 150 bottles staged and the contents appeared to be in first-rate condition.—Cheal Medal.

The contribution from the Women's School at Cocking, Glenside, Sussex, was undoubtedly the most remarkable of a number of the kind, and gave the public a good idea of the work being undertaken. A splendid collection from the school of Lettuces and Cauliflowers especially good. So were the Messrs. Lane Prince, Albert Bramley's Seedling, Cox's Orange Pippin, Peasgood's Nonsuch, Allington Pippin, Lord Derby, and Newton Wonder Apples; the Pears and those sent by Chrysanthemums and Carnations, made up a very bright display. A silver-gilt Knightian Medal was awarded to Mrs. E. Mere for a collection of vegetables and cooked specimens.—Banksian Medal.

Mr. R. STEWARD, Parsfanger Gardens, Herts, exhibited seven varieties of Brussel Sprouts, three plants of each; the sorts were The Duchington, Soldato, Dwarf Gem, Dread nought, Matchless, Liberton, and St. Foin. Soldato bore very large, fine, very fine sprouts.—Silver Banksian Medal. From the R.H.S. Gardens nine dishes of picked Brussels Sprouts were brought, and awards made at the Wisley trials were confirmed, viz., Award of Merit to Dundee (BARR AND SONS), and Favourite (ARTHOGSTAIL). Highly Commended to Dalkeith (SCARFF), Rosny (BARR AND SONS), and Hollow Exhibition (CARTER AND CO.). Commended (not to Perfection (E. W. KING), Darlington (SCARFF), Aylburth Giant (R. VEITCH AND SON), and King of the Market (BARR AND SONS).

Three fine specimens of fruits of Diospyros Kaki were placed on the Committee table, but there was no evidence of ownership.

NATIONAL CHRYSANTHEMUM.

NOVEMBER 13.—The Floral Committee met at Essex Hall, Strand, at 5 p.m. on the above date. There was a fair attendance, and a number of novelties came before the Committee. No Certificate was awarded, but the three following varieties received commendation:

Lizzie Edwardson.—A large yellow single variety, described in our R.H.S. report (p. 210).

Orange Decorative.—This is a large decorative single variety, with blooms 4½ inches across and with the loose, elegant appearance of a small-sized Japanese variety. The colour is light orange-fawn or apricot, with a narrow yellow zone round the eye. These two varieties were shown by Mr. NORMAN DAVIS, Fairfield.

Raymond Dyer.—A brilliantly attractive and striking single variety, and one that produces its tasselled flowers in elegant sprays. The colour is rich, shining, chestnut-red, with a narrow yellow zone around the eye. Shown by Mr. G. STORNEY, Exeter Road, Bournemouth.

After the meeting of the Floral Committee, a sub-committee met and laid plans for the drafting of selections of early-flowering Chrysanthemums and for trials of selected varieties.

At 6 p.m. Mr. Thos. Bevan presided over a meeting of the Executive Committee at the offices of the British Florists' Federation, Covent Garden. Two new members were elected, and the financial statement showed a balance at the time of £57. Prize monies amounting to £46 9s. were passed for payment. The reserve fund is still intact. At the close of formal business, the secretary started a discussion on "Reconstruction." This was carried on briskly for about three-quarters of an hour; many useful suggestions were made, and these will come up for fuller consideration at the next meeting.

SCOTTISH HORTICULTURAL.

OWING to the changes brought about by the war, and to the much more important position which home-grown food plants now occupy in our national economy as compared with pre-war times, it has been decided to replace the Chrysanthemum Exhibition and Winter Flower, Fruit and Vegetable Show which the Scottish Horticultural Association successfully conducted for thirty years by a great Potato Exhibition. Provided the state of the country will permit of its being held, it is proposed to hold this Exhibition in Edinburgh in the autumn of 1919, and should it prove a success, as it is confidently anticipated it will, the intention is to continue it annually thereafter. The arrangements are not yet completed, but a guarantee fund has been formed, a substantial sum has already been promised for prizes, and the prize list is in course of preparation.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

THE monthly meeting of this society was held at the Royal Horticultural Hall on Monday, the 11th inst., Mr. C. H. Curtis presiding.

Before commencing the general business a vote of condolence was passed to the widow of the late Mr. E. J. Allard. The Army Forms relating to the death of the late Pte. F. W. Rogers, V.A.W.A.C., J. Haxhurst, J. W. Nye, and R. Daniels were received, also the death certificates of two other members, and the sum of £105 7s. 6d. was passed for payment to their respective nominees. One member was allowed to withdraw double the amount of his interest, and one member was assisted from the Distress Fund. The sick pay for October on the private side amounted to £61 18s., and on the State side to £53 10s. 6d.

TRADE NOTES.

CHAMBER OF HORTICULTURE.

REPRESENTATIVES of non-trading societies did not turn up in large numbers to the meeting at Dominion House, Norfolk Street, Strand, on Tuesday last, at 2.30 p.m. Chief interest centred in the amount of annual subscription the non-trading societies, such as the various floricultural societies dealing with one special kind of flower, and horticultural societies, should pay if they attached themselves to the Chamber. It was pointed out that most of these societies had suffered severely by depletion of membership and funds during the war, and would need a year or two to recover. This position led to the final agreement that such bodies should pay a maximum annual subscription of two guineas for the next two years, the smaller societies to pay only one guinea, but at the end of 1920 these annual subscriptions should be subject to revision.

ORANGES AND LEMONS.

ON the 18th inst. the Food Controller took under control all the stocks of Oranges and Lemons in the country, and those yet to be

imported. The Covent Garden dealers are resenting control now that hostilities have ceased, and they desire freedom of action. The London dealers, at a meeting held at the Connaught Rooms, passed resolutions calling for the suspension of all Orders concerning the distribution of fruits and vegetables; the withdrawal of the Oranges and Lemons Order; and the removal of the embargo on imports of Apples and other fruits and vegetables. Curiously enough the fruit buyers of Liverpool have pledged themselves to carry out the Oranges and Lemons Order, and disagreed with the London dealers, but the latter protest against the monopoly of Oranges and Lemons which they consider exists in the saleerooms at Liverpool and Manchester.

POTATO ORDER OF 1918.

At the mass meeting of the National Federation of Retail Fruiterers, the London and Provincial Fruit Buyers' Association, and the London and Home Counties Retail Fruiterers' Association, held under the presidency of Sir A. Yeo, at the Connaught Rooms on the 13th inst., a resolution was carried protesting against the Potato Order of 1918, insisting upon the margin of profit as laid down by the trade as a minimum, upon the receipt of 112lb. net of sound, saleable, reliable Potatos to the cwt., and the return of all waste; and demanding the presence upon the Market Distribution Committee of elected representatives of the retailers, with an addendum that all retailers should refuse to sell Potatos unless a living profit were allowed.

CROPS AND STOCK ON THE HOME FARM.

HOUSING CATTLE

Now that pastures are very wet the time has come when the milking cows will be better under cover during the cold nights which will continue for some time to come. Jersey and Guernsey breeds should certainly be housed, but the Shorthorn and various other hardy breeds need not be housed yet, provided the pastures are dry and well sheltered by hedges or other wind breaks, and the weather is reasonably warm for the time of year. Some cowkeepers prefer to leave their Shorthorn cows out of doors all the year round, simply bringing them in for milking only; indeed, many do not even put the cows under cover for calving, but house them for a few days after calving. In this connection everything depends on local custom and conditions.

In my mind there is no doubt whatever as to the wisdom of placing under cover the more tender breeds, commencing with the calves, and following with yearlings, and finally the cows, about the middle of the present month. Some cowkeepers do not allow their cows out in the fields after November, but allow them to run in an open, dry yard for exercise, and feed them entirely with artificial food. I am inclined to believe this is a good plan. Cows turned out during a showery, cold day in December gather in the most sheltered part of the field, where they invariably stand shivering in the cold, and do not attempt to feed. Under such circumstances they cannot be producing a plentiful contribution of milk, whereas if they had the protection of a shed in an open yard, where they could be fed with hay, Oat straw, and Cabbage, with an ample water supply, and obtain exercise for a few hours, the result would more than justify the treatment, and the cows would be less liable to ailments, such as tuberculosis or milk fever.

For the young stock an open yard with a shed having a southern aspect is ideal. Here they obtain air, sunshine and exercise. Fed with Cabbage (not frozen), Mangold, Turnips, rough hay, and sweet Oat Straw, and if possible at least 2 lbs. each of cotton-cake per day, they thrive, and come out in April in strong, healthy condition. An ample water supply is important.

During the winter a substantial ration is an advantage for dairy cows, as it assists them to produce a maximum quantity of milk of high quality. There are those who do not believe in the artificial feeding of cows; they say the food a cow procures naturally, i.e., grass and hay, is sufficient to give good results, but surely a cow fed extra well should give a corresponding return in milk, both as regards quantity and quality. The cream must be richer when extra food rations are provided than from the ordinary grass feed, especially as grass is generally soft and watery in winter time. Good meadow hay, rich in herbage, is a great stand-by for milk cows. The better the quality the higher the returns. Some farmers chaff the hay and mix it with whatever roots are used, but I prefer long hay as giving more employment to the animals, and less liable to cause indigestion, because when chaffed, with roots, the cows are apt to eat hurriedly. I give 6 lbs. at the morning meal while milking, and 10 lbs. at night; 15 lbs. of cut Mangold at each of the two feeds, with 5 lbs. of Cabbage added. Bibby's dairy cake is given at the rate of 2 lbs. per cow at the end of the day, previous to milking.

PIGS

There is a good prospect of obtaining more cereal food for pigs. I am hoping to see the Barley that is too poor for malt or seed released for grinding, and now that Barley is not used with Wheat flour there is hope for the pigs. Pigs should not be neglected, as no other bacon is superior to English grown, fed, and cured.

At a time when many persons are reducing their stock of pigs, I like to increase mine. Much is heard about the extremely low prices of store pigs, but there may be two sides to that subject. In the open market last month I sold eleven week old stores at 42s. each; close by other stores sold at 6s. each. There are pigs *and* pigs. Meal from home grown Barley mixed with boiled small Potatoes is quite the best food for putting on good flesh in pigs, either for pork or bacon. If separated milk can also be added so much the better, but the food should not be made too sloppy. Breeding sows and growing store pigs should have plenty of exercise; my sows have the run of a pasture field all day, and lie in an open, dry shed at night, with plenty of warm, dry straw, and they succeed well. Many farmers assert that if the boar continuously runs with the sows the results are not so good as when the sexes are separated; that is not my experience, and I get an average of ten pigs to a litter from my Large White Yorkshire sows and Middle White boar. This is quite one of the best of the crosses. *E. Molyneux.*

Obituary.

Robertha Henrietta Anderson. Lovers of hardy plants throughout the entire world learn with deep regret of the decease of Miss R. H. Anderson, on Thursday, October 31, at Braikenskimming, Mauchline, Ayrshire. Familiarly known amongst her friends as "Miss Bertha," Miss Anderson made gardening her hobby, and by her example and influence did much to further the cultivation of hardy plants. From a simple utilitarian garden of a type common to country houses, she evolved one which was a joy to herself and a delight to her friends. The garden was pleasantly situated on the high bank of the River Ayr, with broad green walks where soft the footsteps fall. While not interfering with the natural lines of the situation, not forgetful of the requirements of the household in the matter of fruits and vegetables, the borders were filled with hardy herbaceous plants, dwarf shrubs, both deciduous and evergreen, and Roses, all arranged in an unconventional but orderly manner, so that through out the year there was always something of interest to be seen. Broad-minded and catholic in her tastes, Miss Bertha gathered together a wonderful collection of hardy plants, many somewhat rare, and also tested most of the newer introductions, all of which did not justify their claims to permanency. During the war, when her male assistants were called to military service, she worked industriously to keep her garden in order, and it is feared she may have overtaxed her strength, forgetting she had passed three score and ten, as during the past summer it was evident that she was failing in vigour, and latterly was unable to walk to her beloved garden. She is laid to rest in the churchyard of Stair, in which parish Barskimming is situated. Along with a host of other plant lovers I mourn the loss of a kind hearted lady whose friendship will remain as a happy memory, while the warmest sympathy of all is extended to the three ladies who have lost a revered and dear sister. *Jas. Whitton.*

Answers to Correspondents.

DAMAGE TO LOGANBERRY CANES: *G. M.* We find no trace of fungous or insect pests on the canes submitted. The injury appears to be due to the action of some corrosive liquid, or most probably to the intense heat produced by a garden fire burning in close proximity to the Loganberries. The distance to which the flames and fierce heat of bonfires may be carried by wind is not always fully appreciated in gardens, and unexpected damage frequently occurs as a consequence.

FIG TREES. *R. L. B.* Your statement that the trees grow freely points to the roots having received too much moisture, or too stimulating manure. It would be advisable to dig down—say for 3 feet, and ascertain the condition of the border. Figs are gross feeders, and often grow too vigorously. When the new shoots are 1 foot in length, and the second crop of fruit is showing, it is well to pinch out the points of the shoots, and thus help the Figs to swell. Should it be found that the soil at 3 feet deep is too wet, provide a drain to keep the border drier. Do not allow the shoots to be crowded; rather thin them freely to allow the sunlight to enter the tree. The Fig is a sun-loving plant, and needs plenty of warmth.

PEARS FOR ARCHES: *J. E. F.* Pyramid trees would not yield such quick returns as cordons. Well-grown pyramids are very ornamental trees, and in ten years they would no doubt be very attractive, and equally as useful. The weeping form of pyramid is much the best style to plant, i.e., as the tree grows the lateral shoots should be depressed, and in this way the main stem will swell up more freely, whilst the sap will be more equally distributed amongst the branches. In nearly every instance the Quince stock is to be preferred to the Pear stock. Cordons, on the contrary, will yield quicker returns and produce good crops of excellent quality. They may be trained over arches or on walls of moderate height. If trained over arches plenty of room should be allowed. The growth is more simple in the case of cordons and their management in other respects easier. The following list comprises some of the best dessert varieties: Williams' Bon Chrétien, Marguerite Marillat, Louise Bonne of Jersey, Triomphe de Vienne, Thompson's, Beurré Superfin, Conference, Doyenne du Comice, Beurre Dumont, Emile d'Heyst, Marie Louise, Fondante de Thirriot, Gros Morceau, President Barabe, Josephine de Malines, Nouvelle Fulvie, Easter Beurré, Marie Benoist, and, where it thrives, Beurré Bance. The names are given in the order of ripening, and the varieties should succeed in almost all kinds of soil.

SEEDLING SINGLE CHRYSANTHEMUM: *J. L.* The flowers arrived in very poor condition, therefore it would not be fair to express an opinion of the merits of the variety. The colour is pleasing, but the flowers appear to be too thin in texture for market purposes, although they may be very useful in a private establishment where they could be placed in water as soon as cut.

TWELVE BEST HERBACEOUS PLANTS FOR CUT FLOWERS: *J. B.* It is very difficult to say which are the twelve best herbaceous plants for providing cut blooms, and no two persons would be likely to agree on the subject. The following should give a good variety: Lily of the Valley, Iris in variety, Montbretias, single herbaceous Paeonies, Pyrethrums in variety, single and double long-spurred Aquilegias, Chrysanthemum maximum in variety, Erygium planum, Gypsophila paniculata, and the double variety, Helenium Riverton Gem, Papaver nudicaule, and Michaelmas Daisies in variety.

SOME OF THE NEWER ROSES.

LIVING, as I do, in North Lincolnshire with strong soil to grow my Roses in, but with an accompaniment of wet mists and strong winds, I think success here is a strong proof of good constitution in any variety. I have received buds from one of the greatest raisers of Roses in the British Isles, with the request that I would test the varieties in my soil, as I admit. As many readers of the *Gardeners' Chronicle* may also have severe climates to deal with, my experiences, and I have been a Rose grower for half a century, may be useful to them. I propose limiting my remarks to Roses introduced during the past six years, though I may refer to one or two earlier sorts which have done exceptionally well or exceptionally badly here. Starting with the year 1912 there are no Hybrid Perpetual varieties of that year to comment upon.

HYBRID TEA ROSES INTRODUCED IN 1912.

BRITISH QUEEN (McGredy).—A very fine Rose when at its best, a fuller and even more perfect Mrs. Herbert Stevens, but lacking strength of stalk, and here much better on half standards than as a dwarf. My first plants seemed bad growers, but time has improved them in this respect. Very free.

DUCHESS OF SUTHERLAND (A. Dickson).—A fine large Rose, and a good grower. Colour rosy pink, shaded lemon and white.

EARL OF GOSFORD (McGredy).—A good grower, and at its best a very fine Rose; not very free, and the proportion of good blooms not very high. The colour is almost that of Victor Hugo, but it is not so fine in shape.

GEOFFREY HENSLOW (A. Dickson).—A bright orange red variety; a fine flower, but not very free here.

GEORGE DICKSON (A. Dickson).—Undoubtedly the finest dark Rose we have, possibly some relation to Earl of Dufferin. The blooms are large, of good shape, fragrant, and a fine colour. The variety has two faults; it hangs its head owing to the weight and great size of its blooms, and it sometimes gives divided flowers.

KING GEORGE V. (Hugh Dickson).—A fine variety, coloured blackish crimson, and a shade which does not burn in the sun. A good grower, full, and very nearly an exceptionally fine Rose.

LOUISE CATHERINE BRISTAU (Pernet Ducher).—A very lovely coloured variety; a garden Rose, a good grower, free, and most distinct. Coral red, shaded yellow, seems to describe the colour best. Highly recommended.

MME. CHARLES LUTAUD (Pernet-Ducher).—A fairly free, vigorous, yellow Rose, said to be an improved Marquise de Sinety, but here it has not much resemblance to that variety. A better grower, but lacking the fine colour of Marquise de Sinety, and here I have better blooms of the older Rose, though the latter is rather a "stumpy" grower.

MRS. RICHARD DRAPER (Hugh Dickson).—This has the style of La France, but is fuller, and a fine show Rose when at its best.

MRS. SAM ROSS (Hugh Dickson).—A very lovely pale yellow Rose, but only a moderate grower here, otherwise it is a good all-round variety.

MRS. WALLACE ROWE (McGredy).—A very good pink variety, fine in shape, and full; not "Sweet Pea mauve." A rather thick, short grower.

OPHELIA (W. Paul).—A first-rate Rose of good shape, colour, and growth; salmon flesh colour, at times almost yellow towards the centre, not too full, but a fine garden Rose.

ST. HELENA (E. Cants).—A very creamy coloured Rose, generally with a pink tinge in the centre; fine shape, full, and a fine grower.

SUNBURST (Pernet Ducher).—A grand Rose when at its best, full, bold, of fine shape, deep cadmium yellow in colour; a good grower and free. Unfortunately it often comes very pale, even white, early in the season. Nevertheless it is worth growing in the most limited collection.

OTHER ROSES OF 1912.

MRS. HERBERT HAWKSWORTH (Alex. Dickson).—This Rose is by some classed as an H.P., but it is really a true Tea, and a good one. In the raiser's catalogue it is described as "delicate cerise on milk-white." Here it is deeper in colour, almost as yellow as Alex. Hill Gray. It is a good grower, with full, globular blooms, which last well.

RODHATE (Poulson).—A red Polyantha (dwarf), very free, and in its best colour very bright. It sometimes comes a duller shade.

CORONATION (Turner).—A bright crimson-scarlet Wichuraiana variety, streaked white. Free and good, though to my taste the white streaks are a considerable defect.

ETHEL (Turner).—A lovely pink Wichuraiana Rose, with good foliage, and excellent in every respect.

SILVER MOON (?).—A large and striking single Wichuraiana Rose, rather perhaps in the style of Una; silvery white; not so strong a grower, I think, as some.

SOPHIA (Weigand).—A fine red variety, with large trusses, not perhaps quite so strong a grower as some, but very good.

CLIMBING RICHMOND (A. Dickson).—A valuable striped H.T., much more free than Climbing Liberty. Flowers as in the dwarf form.

SWEET LAVENDER (Paul and Son).—A striking climber for those who like the colour. It is very distinct, and its golden stamens add to the effect.

ROSES INTRODUCED IN 1915.

CORONATION (Hugh Dickson).—A very large and fine flower, of a pale pink shade, sometimes deeper; a very vigorous grower; very striking. One of the few Hybrid Perpetuals to gain a Gold Medal in recent years.

The following are Hybrid Teas:—

CISSIE EASLEA (Pernet Ducher).—Saffron yellow, sometimes with rosy centre; a Rose of good size and shape, fairly full; a good grower, and a valuable garden variety.

DUCHESS OF NORMANDY (Le Cornu).—A sport from that grand Rose Dean Hole, and identical except that it is shaded with yellow on salmon flesh.

EDITH PART (McGredy).—A beautiful Rose, of medium size; excellent in growth and habit. The

FIG. 34.—HYBRID TEA ROSE QUEEN MARY: COLOUR OF FLOWER YELLOW, SHADED WITH CARMINE.

colour varies somewhat, usually salmon-yellow shaded rich red; quite distinct.

H. E. RICHARDSON (Hugh Dickson).—A richly coloured crimson Rose, and a good grower. Here it lacks size and does not give full blooms.

LADY MARY WARD (McGredy).—A lovely deep yellow Rose, free and striking, but it hangs its head, and is not very strong in constitution.

MARIE ADELAIDE (GRANDE DUCHESSE DE LUXEMBOURG (Soupert et Notting).—A very lovely Rose, deep yellow, and of beautiful shape; a fairly good grower and very free. Not very large.

MEVROUW DORA VAN TETS (Leenders).—Bright crimson, not full, and of medium size. A useful garden Rose.

MRS. ANDREW CARNEGIE (Cooper).—When I saw the blooms which won the Gold Medal in 1912 I thought them the finest white Roses I had ever seen. In 1913 it did not seem so good. I have seen two rows of this in a nursery one mass of fine blooms, yet it has not done well here so far. I suppose the climate or soil does not suit it, but I am still trying it.

QUEEN MARY (Alex. Dickson) (see fig. 84).—At first this Rose seemed rather like Juliet, but it is quite distinct; the colour is yellow, shaded carmine. It is very free, rather hangs its head; a fair grower only, but exceptionally beautiful.

WILLOWMERE (Pernet-Ducher).—A lovely shrimp-pink Rose, with yellow and deep pink shadings. In some ways an improved Lyon, and certainly more reliable in the garden. A good grower, free, large, and one of the best. Perhaps not quite so full as Lyon, but it has not the Lyon's eccentricities.

Other Roses of 1913.

MAIL EDOUARD HERRIOT (*The Daily Mail* Rose) (Pernet-Ducher).—When this Pernetiana Rose first came out one of our greatest commercial Rose growers said it was "the best Rose anyone ever brought out!" The colour is remarkable, a bright prawn-red. The blooms are of good shape but not very full; a good grower, hardy, and with good foliage. Its great fault is that, although the blooms are not heavy, they

FIG. 83.—HT. ROSE MRS. CHARLES E. PEARSON. (SEE P. 213.)

almost always hang their heads. It is possible that the new Flame of Fire may be preferable.

GEORGE ELGER (Turbat).—The best yellow dwarf Polyantha; very free and good. An advance.

IRISH FIREFLAME (Alex. Dickson).—A splendid advance in colour among singles; a deeper orange and red Irish Elegance; very free and striking. Unsurpassed for table decoration.

MRS. M. H. WALSH (Walsh).—A grand pure white, double, climbing Wichuraiana, free, and fine in foliage; not so strong a grower but a great improvement in purity of colour on White Dorothy.

DANAE (Pemberton).—A yellow hybrid Rose, a continuous flowerer, and good generally, though not so strong a grower as the Wichuraianas.

MOONLIGHT (Pemberton).—Flowers lemon and white, with golden stamens; another free flowerer, of medium growth. *L. C. R. Norris-Elye, Utterby Manor, Louth, Lincolnshire.*

(To be continued.)

MRS. C. E. PEARSON (McGredy) (see fig. 83).—An extraordinarily beautiful Rose, somewhat after the colour of Lyon, but not so large; holds its head up well, fine shape, and free. Only a medium grower.

MRS. F. W. VANDERBILT (McGredy).—Almost my favourite Rose. In colour a mixture of orange, apricot and red; fine shape, free, of good size and vigorous. Its growth is apt to be lopsided, and this is almost its only fault.

MRS. R. D. MCCLURE (Hugh Dickson).—Another fine Rose; salmon-pink, of splendid shape, large; a good grower and good all-round.

MRS. T. HILLAS (Pernet-Ducher).—A good garden Rose, and at times fit for show purposes. Yellow, sometimes rather pale; a good grower and decidedly useful.

OLD GOLD (McGredy).—Almost a single Rose, but very lovely in the bud and when half opened. The colour is a rich mixture of orange, apricot and red. A good grower and very free. Splendid for cut flowers if taken early enough

CULTURAL NOTES

THE FORCING OF RHUBARB AND SEAKALE.

To obtain forced Rhubarb by Christmas the crowns need not be lifted, but a cask or large box should be turned upside down over them. Make a hole in the upper end for ventilation, and then surround the cask or box with a hot bed. This may consist of a mixture of manure and leaves or anything else that will ferment. The material should extend 3 or 4 feet beyond the cask, and it should be made into a firm heap about 4 feet in depth. The heat of fermentation will warm the soil about the roots, and the stems will grow freely and strongly. If two or three roots are covered every three weeks or so a constant supply will be maintained. Should the heat decline before growth is finished place a quantity of fresh manure around the cask; in frosty weather the whole may be covered with straw or Bracken. If the casks are left in position until the spring they will protect the crowns, the roots of which will grow afresh in summer and the plants show little indication of having been forced at such an unreasonable time.

Seakale may be had in December by treating it in the same manner as Rhubarb, or large pots may be placed over the crowns. This vegetable must be well blanched, and should always be forced in the dark, but the interior of the pots must be ventilated a little to prevent the growth decaying. For midwinter forcing lift the roots, place a number of them in a 10-inch or 12-inch pot, and plunge the pot in a hot bed in a Mushroomhouse or suitable pit. The earliest plants only should be lifted at present, and, as soon as the leaves have withered from the crowns the roots may be taken up and potted, and some of them may be put in now and again as the demand requires. The roots do not need much water when being forced. If the crowns are preserved after forcing they will be useful for purposes of propagation. *James A. Paice.*

BULB GARDEN.

CROCUS HYEMALIS.

CROCUS HYEMALIS, a delicate-looking species from the Near East derives much of its interest and value from the circumstance that it blooms in mid-winter, frequently in December and January. It is a charming plant for the sheltered, sunny rock garden, the front of the border, or for growing in pots in the cold or cool greenhouse. The flowers are of great beauty, for the white segments are lined with purple and the filaments are like gold wire. In the rare variety Foxii the anthers are black, and these add greatly to the fascinations of this form of the Winter-flowering Crocus.

The short days of mid winter, even when fine, are too sunless to induce the flowers to open unless in exceptionally fine weather, and it is always wise to give plants out-of-doors the protection of a hand-light or bell-glass from the time the buds appear until the flowers are over. Unless this is done the probabilities are that the somewhat thin flowers will be reduced to pulp in a short time, and without ever showing their great beauty.

C. hyemalis is a gem for the alpine house or cool or cold greenhouse. From six to twelve corms may be placed in each pot early in autumn about half-an-inch beneath the surface of the soil and plunged in a bed of ashes until about the end of October, when the plants may be taken indoors and grown in a cool, sunny position. Corms planted out-of-doors should be set about 1 inch deep.

I have found C. hyemalis hardy in ordinary seasons, but in exceptional winters the leaves are destroyed before the corms have fully ripened, and the glass protection suggested for the flowers is desirable for the foliage also in such seasons. *S. Arnott.*

TREES AND SHRUBS.

CASTANOPSIS CHRYSOPHYLLA VAR. OBOVATA.

CASTANOPSIS, a genus of about 25 species, all except one natives of warm countries in Eastern Asia, is known only in gardens by the one Western species, C. chrysophylla, the Golden-leaved Chestnut or Chinquapin, a native of California. According to Sir Joseph Hooker, Castanopsis is inseparable from Quercus by any constant character. The fruit of C. chrysophylla is, however, like that of the Chestnut. The tree is evergreen, the leaves lanceolate entire, green above, and coated below with golden-yellow, persistent scales. Sargent states that it grows to 100 feet or 150 feet in height in the humid coast valleys of Northern California, but is shrubby at high elevations. In this country, where it has been in cultivation about 75 years, it is more a shrub than a tree. Only this type was known until quite recently, when Messrs. T. Smith and Son, Newry, sent us a branch of what they called C. obovata (see fig. 56), which they said had appeared among a batch of plants raised from seeds imported from North America. The difference in habit and foliage from the type is remarkable, the plant being dwarf and spreading, and the leaves, as shown in the illustration, almost round. They are golden beneath. If this be a seminal sport from C. chrysophylla and there seems no reason to doubt that such is its origin, it is one of the most striking mutations that have been recorded. There is just the possibility that it is the result of chance pollination with some kind of Oak. It would be interesting to ascertain the exact source of the seeds from which the plant was raised in Messrs. Smith and Son's nursery. We are informed that plants of C. obovata are in cultivation at Edinburgh and Kew.

ASIATIC MOUNTAIN ASHES.

The Bulletin of Popular Information, No. 2, Vol. IV., issued by the Arnold Arboretum, contains the following interesting account of Asiatic Mountain Ashes grown in the Arboretum:

In recent years a number of these trees have been brought from eastern Asia to the Arboretum, and some of them promise to be valuable trees here. The Japanese Sorbus commixta was the first of them which was planted here, and it has now been growing in the Arboretum since 1892. There is a tall specimen of this species on the right hand side of the path leading to the Shrub Collection from the Forest Hills Gate. It has smaller flower-clusters than the European species, the bright red fruit is smaller, and its chief value is in the bright orange and red colour of the leaves in autumn. A much handsomer plant is Sorbus pekinensis, a native of northern China, which is now well established in the Arboretum. It is a slender tree with narrow leaflets, compact clusters of flowers and lustrous pink or yellowish fruit in drooping clusters. The colour of the fruit is unusual among Mountain Ashes. The narrow leaflets give this tree a particularly open and attractive appearance. There are a number of specimens in the Sorbus Collection in the new ground near the group of Swamp White Oaks on the Valley Road, but the largest and handsomest specimen in the Arboretum is in the nursery plantation near the top of Peter's Hill. Sorbus Koehneana has flowered and fruited in the Arboretum this year for the first time. It is a shrub now about 3 feet high with slender erect stems, small leaves with numerous narrow leaflets, small compact clusters of flowers, and snow white fruit. It is a beautiful shrub which when better known will become common in gardens. The plants in the Arboretum were raised from seeds collected by William Purdom in northern Shensi. Sorbus pohuashanensis, so named because it was discovered on the Pohua Mountains in northern China, is also well established in the Arboretum. The leaflets are rather broader than those of the Rowan tree, but it has the red fruit and woolly buds of that species and is not superior to it for general cultivation. Although they are not as large and shapely trees as some of the Old World species, the two Mountain Ashes of eastern North America, Sorbus americana and its variety decora, have no rivals in this group in the beauty of the great drooping clusters of orange fruit and in the orange and red tints of their autumn foliage. They are small trees or large shrubs, and are often planted in gardens in Canada, northern Michigan and Minnesota, but unfortunately are still little known in those of eastern Massachusetts.

SILVER LEAF DISEASE.

THE evidence that Silver Leaf is a fatal disease is now overwhelming. Trees once attacked are killed outright. The need of drastic measures in dealing with a malady that threatens to destroy all our Plum trees and

FIG. 56.—CASTANOPSIS CHRYSOPHYLLA VAR. OBOVATA.

which may spread to other fruits, such as Apples, Cherries, Pears and Apricots, is therefore pressing. The removal of affected branches does not arrest the progress of the disease, and the recommendation to save all diseased branches in the belief that trees can thereby be saved does not go far enough.

The compiler of the Board of Agriculture Leaflet No. 302, issued in 1915, had not then realised the deadliness of Silver Leaf. But in Leaflet No. 58, recently issued by the Food Production Department, its seriousness is recognised, and we are told that "unless drastic measures are taken to prevent its spread, one of the most valuable varieties of Plum, namely Victoria, is threatened with total extinction." But we are also told that "if the affected trees are systematically and energetically dealt with it is possible very largely to control the disease," and cutting out the silvered branches of trees otherwise healthy is recommended as a means of saving them. This has been tried again and again, but the trees have sooner or later been killed outright by the disease. Every tree therefore which develops the silvered foliage characteristic of this disease should be looked upon as stricken beyond recovery, and be destroyed at once.

The directions given in Leaflet No. 58 respecting the removal of branches had better not be heeded, and those for the removal of dead or dying trees be adopted for all affected trees. These directions are:—

"Dead or dying trees should be completely grubbed up. If it is quite impracticable to take such trees up by the roots they should be cut down close to the ground and the stump covered with at least 6 inches of soil. Exposed stumps on which the fungus can fructify should never be left. Trees that have been grubbed up should be removed from the plantation immediately and be used for firewood. If it is necessary to keep the firewood for any time, it should be stored as far away as possible from fruit trees and preferably in a shed. To cut down dead trees without subsequently removing them is utterly useless, and to keep a wood pile in or near a fruit garden is a practice that cannot be too strongly condemned.

"The success of the above measure largely depends upon the co-operation of all fruit growers, including the owners of fruit trees in private gardens. Neglected fruit plantations are not only a great danger to other trees, but also to those orchards which are maintained in a proper sanitary condition. In view of the threatening character which Silver Leaf disease has assumed, it is earnestly hoped that an active campaign against it on the lines indicated above will be commenced and maintained in all parts of the country."

The suggestion that the disease affects only grafted trees (see p. 148) is not supported by the behaviour of trees on their own roots, Portugal Laurel, for example, of which hundreds of bushes have been destroyed by Silver Leaf. Seedling Plums are also attacked, and bushes

of the double flowered variety of Prunus triloba raised from sucker shoots have been killed after a healthy existence of many years. Moreover, Plums are rarely propagated by grafting, budding being practised almost universally.

There is little doubt now that Silver Leaf is caused by the fungus Stereum purpureum, which, as Leaflet No. 58 states, exists in the wood of the branches, and ultimately fructifies on the dead bark, when it produces myriads of spores, which are the means of spreading infection to other trees. The spores are distributed by wind, and that they are carried long distances is proved by the development of the disease on isolated Plum trees far removed from any likely source of infection. When gardeners look upon a Plum tree with Silver Leaf as they would a mad dog or a fox in the poultry yard, we may hope for the extermination of the disease. W. W.

IN the *Gardeners' Chronicle* and in the *Journal of the Board of Agriculture* concern has recently been shown with regard to the spread of Silver-Leaf disease. It has not always, I think, been clearly pointed out that Silver Leaf is due to the fungus, Stereum purpureum, which is fairly common and may be found probably in most plantations. I would suggest that it is necessary to trouble about the extermination of Stereum purpureum rather than to worry about the treatment of fruit trees. I do not believe that Silver Leaf is largely due to the transmission of the fungus from one fruit tree to another. Fresh infestations arise only from spores, and it must be a very roughly cared-for plantation of fruit trees if dead wood is allowed that will enable the Stereum to fructify. Practically, I suppose, one may say that Stereum purpureum is never found in a state of maturity in a plantation of Apples or Plums. The source of disease, therefore, must be sought in neighbouring plantations, and very probably the spores may be wafted from a great distance. It seems scarcely to be realised by some writers that Silver Leaf disease is well known to be due to the mycelium or spawn of a perfectly well known fungus. There is not only the one cause, but there is, further, only one means of increase, viz., by spores. It is true that the spores germinate and attack the tree through a wound, which can be protected, so that the treatment of wounds with tar will prevent communication of the disease, but, nevertheless, the best insurance, no doubt, is that of destroying the source of the spores. *R. Irwin Lynch.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM LADY VEITCH.

AT the meeting of the Royal Horticultural Society on the 5th inst. the Orchid Committee awarded a First-class Certificate to Odontoglossum Lady Veitch (see fig. 87), which was pronounced to be the best Odontoglossum of the year. The raisers, Messrs. Armstrong and Brown, obtained Odontoglossum Lady Veitch by crossing O. Hylandianum and O. Armstrongiae, two specially fine varieties, the exact record of the parentage of which is not available, although a fine form of O. Wilckeanum is known to have entered into the lineage, and in this case, as with some of the famous Vuylstekeae hybrids, it has had excellent effect.

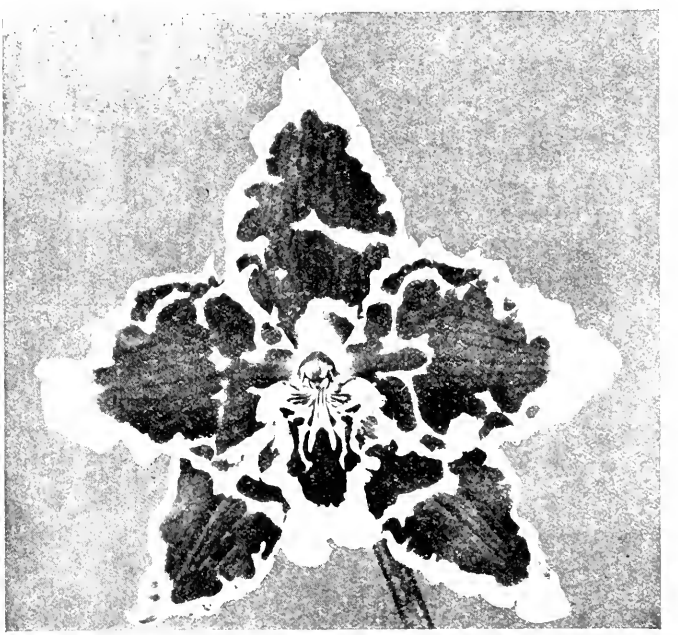

FIG. 87.—ODONTOGLOSSUM LADY VEITCH.

The ground of the flower is clear white; the rich blotching on the inner two-thirds of the segments are deep claret purple, the colour pervading the whole of the substance of the flower and appearing on the reverse side almost as bright as on the face. The crest of the lip is yellow and the upper surface of the column dark purple.

LAELIO-CATTLEYA SUNBEAM.

THIS hybrid between C. Tankervilliae (bicolor × Rex) and L. C. wisetonensis (C. Warneri × L. C. callistoglossa), sent by C. J. Lucas, Esq., Wareham Court, Horsham, has pink flowers tinged with yellow, the narrow elongated lip being derived from C. bicolor. The lip is yellow in the centre and marked with purple in front.

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Cucumbers. — Cucumber plants in bearing which will be discarded as soon as the house is needed for other purposes should be grown in a temperature of 65° to 70° by night and proportionately warmer by day. They may be more liberally fed and top-dressed frequently with a rich compost that should be warmed before it is applied to the roots. Keep the plants scrupulously clean, and husband their strength by removing all young fruits that are not likely to be wanted; the latter precaution is especially needful where the demand for Cucumbers will be heavy from January onwards. If tree leaves are used wholly or even partially for making the hot bed, syringing will scarcely be necessary. Water warmed to 30° or 85° may be used freely where moisture is necessary; give plants in bearing warm, diluted liquid manure. The vapour arising from the beds helps to keep the plants in good health, and prevents the spread of red spider.

Celery. — Late Celery which has not been earthed up finally should be attended to at the first opportunity, as much further growth cannot be expected after this date. Choose a fine day for carrying out this work. Hold the heads together with the hands or temporarily tie the leaves to prevent soil from entering the hearts of the plants. Shallow planting and high moulding are best on heavy, wet soils, and generally no further protection need be afforded. Provided the ridge is rounded and made smooth, rain and snow water will pass away into the alleys on either side. When Celery is planted four or more rows wide in broad trenches it can be protected with mats, thatched hurdles, or similar materials.

Cauliflowers of the Autumn Giant kinds are still plentiful and good; the mild season has enabled the latest plants to mature good sized heads. Early winter protecting kinds are forming heads, which should shortly be plentiful, provided the weather continues mild. Ventilate freely plants of the Early London type which have been pricked out in frames or in temporary beds, and continue to transplant others where they will receive a little protection in cold weather.

Mustard and Cress. Continue to sow these salads weekly to maintain a constant supply. Place the boxes containing the seeds in a temperature of 55° or 60°.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Calanthe. — Deciduous Calanthes of the Veitchii and vestita sections, together with their hybrids, are opening their flowers. The period of blooming will be extended if the plants are removed from their warm, growing quarters to a cooler and drier house. The Cattleya house is suitable, and the Calanthes may be arranged amongst the other occupants. The plants will make a bright display for some weeks to come, and the spikes will last longer after they are cut than when grown in a warm, moist atmosphere. After the spikes are cut let the plants have a complete rest, placing them on a dry shelf near the roof-glass. The temperature should not fall below 55°. Withhold water from the roots until the plants start into growth again in the spring.

Phaius.—The various species of Phaius are growing freely, but from now onwards until the early spring they will, provided their surroundings are kept moist, require very little water at the roots; endeavour to keep the compost just damp. P. Cooksonii, P. Norman, P. Marthae, and P. amabilis are beautiful hybrids, and very floriferous; they require far less room than plants of P. grandifolius and varieties of P. assamicus. Phaio-Calanthe Sedeniana, P.-C. Colmanii, P.-C. Arnoldiae, and P. C. Berryana

should be afforded similar treatment to the above. These plants are very subject to attacks of thrip and scale insects, which should be kept in check by sponging the leaves frequently with an insecticide. The plants should be grown in an intermediate temperature, and afforded plenty of fresh air at all times, but they must not be exposed to cold draughts.

Phalaenopsis.—P. amabilis, P. Sanderiana, P. Schilleriana, P. Stuartiana, and P. leucorhoda are in flower or developing flower-spikes. The plants should be watered with great care during the winter, as an excess of moisture at the roots may set up decay in the leaves. Examine the plants each morning, and, if the Sphagnum-moss is dry, sprinkle it with clear water as soon as the temperature rises to 65°. At the same time damp the outsides of the receptacles and the roots that are clinging to them with tepid rain-water. Take care that water does not lodge in the centres of the plants or in the axils of the leaves. Do not retain the flower-spikes for long after the flowers have developed or the plants will be weakened and permanently injured. These Orchids should be grown in a light situation, but not exposed to direct sunshine, even at this season. The surroundings of the plants should be damped once or twice daily, regulating the amount of moisture according to the weather. The late spaces of the house should be allowed to become dry for a short time during the middle of the day. The night temperature of the house during mild weather should be about 65°, with a rise of 5° during the day; on very cold nights when much fire-heat is necessary, a few degrees lower will suffice. Admit fresh air to the house without causing cold draughts, opening the top ventilators slightly on the side of the house sheltered from the wind.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Humea elegans. Plants of Humea elegans that require repotting may be attended to now. Use a light, open compost, such as a mixture of fibrous loam, leaf-mould, manure from a spent Mushroom-bed, lime rubble and sand. See that the pots are clean and efficiently drained, as it is most important that surplus water should pass away freely. When potted place the plants on a base of coal-ashes or gravel near the roof-glass. During the next few months Humeas require very careful treatment. Water should be given only when the plants are absolutely in need of moisture. Admit air through the top ventilators whenever the weather is favourable, and use fire-heat sparingly at all times.

Cyclamen. The earliest plants of Cyclamen latifolium are coming into flower, and need careful watering and feeding. They may be given liquid manure and a concentrated fertiliser at every alternate watering, but water must not reach the centres of the plants, or many of the flowers will damp off. Examine the plants once a week and remove faded flowers and decayed leaves. During the winter months Cyclamens should be grown in a light, airy house near the roof-glass. Give them plenty of air whenever the weather is favourable, admitting a little through the top ventilators during the night. Keep young seedling plants growing near the roof-glass in a house having a temperature of about 50°.

Perpetual-flowering Carnations. As soon as suitable cuttings are available a good batch may be inserted; shoots taken from the flower-stems are best for the purpose. The flowering plants are well rooted, and stimulants may be given them more liberally than hitherto. Diluted soot-water is an excellent stimulant for Carnations, and this may be used once a fortnight. Keep a sharp watch for red spider, and take measures to destroy the pest as soon as it is detected. Fresh air is essential to the well-being of Carnations, and this must be given more or less according to the weather. A temperature of from 45° to 50° is ample except during times of bright sunshine, when 10° higher may be allowed. Aphis may be kept in check by light fumigations with nicotine.

Souvenir de la Malmaison Carnations. "Malmaison" Carnations should not be grown with the perpetual varieties, as they require cool conditions at all times. Fire-heat should not be used except when severe frost threatens, and then only to keep the thermometer from falling below freezing point. Water the plants sparingly for the next two or three months, and grow them near to the roof-glass. Syringe them with a fungicide occasionally to keep them free from disease.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Out-door Vines.—Vines out-of-doors should be pruned, and nailed or tied, as the case may be. Do not lay the wood in too thickly, but depend on young shoots rather than upon old spurs. Young Vines that have been planted within the past year or two should be allowed to extend themselves. No protection need be given, as Vines are hardy in this country. Examine the borders, prick up the surface soil, and give a light top-dressing. If the soil is dry give it a good watering.

Out-door Figs.—These should now be pruned, removing all the green, succulent wood and retaining well-ripened growth. In districts where frosts are found to be injurious to Figs it will be well to bunch the growths together and then protect them with straw to a moderate extent. Apply a light mulch around the base of the stems and water the roots if necessary. Should the Fig trees have made extra strong growth, some root-pruning will be desirable, but leave this (for preference) until the spring.

Fruit-Room. There are not many fruit-rooms with an excess of fruit in them this season, therefore close attention should be given to the few fruits in the store-room. Remove all slightly-damaged fruits, and use them as quickly as possible. Make the most of what few Pears there may be. Apples will prove very valuable a few weeks later.

American Blight. Of all insects that are troubling the fruit-cultivator none is worse than American Blight. I repeat my former advice to take speedy, and when necessary extreme measures to destroy the pest. Two dressings with spray fluids at a maximum strength will be needed, and in extreme cases, where the trees are easily accessible, apply the paraffin and soft-soap emulsion previously advised, but syringe with hot water in advance of this application for the sake of its penetrating power. Where orchard trees are not easily accessible, and are infested with blight, it will be expedient to cut down the trees and burn them, especially if they have passed their best condition of bearing. In the case of younger trees it may be found expedient to cut them back and re-graft them in the spring.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMESTER, Keele Hall, Newcastle, Staffordshire.

Pot Figs. It is not advisable to commence the forcing of pot Figs so early as usual in view of the restricted fuel supply. Fire-heat is not necessary for the first fortnight; a temperature of 45° is suitable, and the warmth should not exceed 50°. If the pots are stood (not plunged) on a bed of leaves or leaves and manure the roots will receive sufficient warmth, provided the fermenting material is moved occasionally. Syringe the trees lightly in the forenoons of fine days and water the roots very sparingly. When the buds commence to break plunge the pots to their rims in a bed of fresh leaves and stable litter to afford a bottom heat of 70°. At this stage the night temperature should not fall below 50°, but be increased gradually to 60° when the fruits begin to swell. Considerable economy in fuel may be effected by keeping the trees in a cool house for another month or six weeks.

Successional Fig Trees. Successional and late trees in pots are defoliated. If the shoots have been well thinned and pinched during the summer very little pruning will be required beyond removing an occasional weak shoot. Let the plants be washed carefully with Gishurst compound or soapy water. Use a soft paint-brush for the cleansing process, as a hard brush might damage the points of the shoots and embryo fruits. Every joint, crevice, and shoot should be painted down to the surface of the soil. Place the trees on an ash surface in a cool, frost-proof house. Water the roots sparingly from now onwards, and ventilate the house freely day and night during mild weather.

Established Fig Trees. Fig trees planted in inside borders intended for starting in the New Year should be cleansed and washed forthwith. The large tree at Keele fills the whole of a large house, and the pruning will be limited to the removal of a few old, exhausted shoots to provide room for new, basal growths. Every branch should be loosened from the trellis and carefully washed with soapy water or an insecticide. Trees trained near the roof-glass get very dirty, and unless stringent precautions are taken to have the trees thoroughly clean, scale, red spider and other insect pests will be troublesome next year. Figs under complete control are not difficult to manage, and failure to produce fruit is undoubtedly usually attributable to a too free root-run, which encourages the development of strong, fruitless growths. Root-pruning should be done directly the last crop of fruit has been gathered, and if still in arrears the work should be finished forthwith. When top-dressing the borders remove the old mulching material and exhausted soil, and replace with a compost of good turfy loam mixed with bone-meal and mortar rubble. If the soil is dry, first water the border, otherwise one watering will suffice after the new top-dressing is applied. Keep the house as cool and airy as possible until the time arrives for starting the trees into growth.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

The Rockery. It occasionally happens that alterations are called for in the rock garden, and these may be carried out during the present month. It will be found a good method to finish a certain amount of work each day, lest a change of weather should cause the work to stand over for an indefinite period, and in the end call for labour at a period when it would be difficult to supply it. Routine work at present consists in clearing away all fallen and dead leaves, providing protecting material for tender plants, cutting over deciduous Ferns and other subjects, and leaving the whole in a trim, neat condition for the winter. Helleborus latifolius is in full flower, H. angustifolius showing white in the buds, and "coloured" forms approaching flowering. Snowdrops, Primula Juliae, and a few other easily excited plants are exhibiting signs of growth.

Roses. If it is intended to apply protective material to Roses it is now full time to do so. The use of rank, strawy manure in dressed grounds is very unsightly, and when the point has been pressed for a reason why Roses above all other flowering shrubs should be treated in that way I have never had a satisfactory reply. Dry bracken is equally efficient for protecting the stems, and not an eyesore, and to more thoroughly protect the plants close to the ground a little heap of soil. I use old compost put to each, never fails in its purpose. It is remarkable what a power of resistance against cold or the effects of cold such a simple material possesses. Flaky leaf-mould is also excellent for the purpose.

Lily-of-the-Valley. Our large plantations of Lily of the Valley got so weed-infested that the crowns had to be lifted this year. Fortin's variety was overhauled and the best clumps replanted in September, and about the present date I hope to replant the common variety. Only the best crowns are kept, and these are planted in long lines at 12 inches apart and 4 inches between the lines, the tips of the crowns being just covered with soil. They are made firm in the soil with the foot as the work proceeds, and some well-decayed manure is worked into the ground as planting progresses. Why, it may be asked, should a common form be cultivated when the much superior Fortin's variety can be had in quantity. One reason is that the latter is late in flowering, though the season may be, and is, extended by planting in various positions, thus making a difference of a few weeks in flowering.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News. *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations. — *The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

APPOINTMENTS FOR DECEMBER.

MONDAY, DECEMBER 2—
Chamber of Horticulture meeting at Caxton Hall.

TUESDAY, DECEMBER 3—
Roy. Hort. Soc.'s Comms. meet. Horticultural Club Com. meets at 3.30 p.m. at 2, Whitehall Court. British Carnation Soc. annual meet., 5 p.m., at 35, Wellington Street, Covent Garden.

MONDAY, DECEMBER 9
United Hort. B. & P. Soc. Com. meet

WEDNESDAY, DECEMBER 25—
Christmas Day.

THURSDAY, DECEMBER 26—
Bank Holiday.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 41.2°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, November 27, 10 a.m.: Bar. 29.9, temp. 46°. Weather—Dull.

Rural Reconstruction.

The first speech of the Prime Minister's election campaign dealt on broad lines with the problem of agricultural and horticultural development. It is of profound significance that the Prime Minister should have put in the very forefront of his programme the need for rural reconstruction. Nobody will dispute his view that the maintenance of the nation as a whole must depend upon a vigorous and populous countryside. As the Prime Minister pointed out, the industries of the nation are constantly recruiting their man power from the rural population, so that even looking at the problem from the industrial point of view, the larger the source of recruitment the more will industries flourish. It is not to be expected that the Prime Minister should at this stage produce detailed plans illustrating the method whereby this desirable state of affairs is to be achieved. Nevertheless, the indications which he gave are of great interest. In the forefront he places better housing and higher wages; he proceeds to indicate what are the means whereby the agricultural and horticultural industries may be able to support the increased charges which they are bound to be called upon to sustain. The solution which he advocates is greater production and less costly methods of transport. Economy in production is apparently to be effected by State control of fertilisers, and if State control can be made to result in a reduced cost and extended use of fertilisers, there is no doubt but that production will be increased.

Improved methods of cultivation are to be sought in the closer association of agricultural and horticultural science with practice, and here again it cannot be doubted that although the best cultivators of this country have little to learn in the way of scientific production, the average production of the country would be raised if a knowledge of scientific principles of agriculture and horticulture were more widely diffused.

The subject of transport is one which will appeal greatly to the producer, and it is along the lines of more economical transportation of produce, and also of raw materials, that greater economy in production may be reached. This last subject is of such importance that we trust the Chamber of Horticulture will lose no time in taking it into consideration and in drawing up a report illustrative of the present cost of the transport of horticultural produce and indicating ways in which reform may be achieved.

The Prime Minister discloses the intention of making large provision for small holdings on which are to be settled returned ex-Service men. So far, at all events, as specialised, that is to say, horticultural small holdings, are concerned, it is to be hoped that the problem will be dealt with along common-sense lines. To spread promiscuously small holdings over the countryside will be bound to lead to failure. The proper procedure is to make a survey of all those districts in which soil and climatic conditions are favourable to intensive cultivation; to select from among them those districts which are well watered and are either provided with, or are capable of being provided with, transport facilities, and then to make a further selection so that only those districts shall be chosen for holdings which are placed in favourable conditions with respect to markets.

Once the capacity and requirements of the market are known, the type of intensively cultivated holdings can be determined, and it is to be assumed that the small holders with full information with respect to those crops for which a large and near demand exists will be prepared to specialise in the growing of them.

Lastly comes the selection of men and the grouping of holdings into what may be called economic units; that is to say, colonies of holdings sufficiently numerous and large to admit of the bulking of produce, and sufficiently progressive to be prepared to grow a limited number of varieties of a limited number of crops. To make a scheme successful, it will be desirable that all the holders to be established in a given district, or at all events those who were not highly trained already, should work for a time under the direction of a practical expert before proceeding to undertake the cultivation of their own holdings.

Chamber of Horticulture.—A meeting to which representatives of all horticultural interests are invited will be held, under the auspices of the Chamber of Horticulture, in the Council Chamber, Caxton Hall, Westminster, on Monday, December 2, at 2.15 p.m. The President of the Board of Agriculture, the Rt. Hon. R. E. PROTHERO, has expressed his intention of being present at this meeting.

Linnean Society.—At the general meeting of the Linnean Society of London, held on the 7th inst., Mr. ARTHUR WARWICK SUTTON, J.P., V.M.H., was, upon the nomination of the Council, elected to fill the vacancy in the Council caused by the death of the late Professor GEORGE PLIMMER, F.R.S.

Lead Nitrate as a Fertiliser.—According to experiments conducted in America small quantities of an aqueous solution of lead nitrate stimulate the growth of plants. The maximum effect was produced when 0.5 grams of lead nitrate per litre of nutritive solution was used (1·60 oz. to 1¾ pint). In experiments in open ground the lead nitrate was used as a fine powder and mixed with a fertiliser to be used as a top-dressing. Though successful in the cases of Beet, Wheat, Oats, Peas, etc., the use of lead nitrate produced no beneficial effect with Potatos.

Cinemas and Cultivation.—The Report of the Minister of Agriculture (Ontario) for 1917 records the systematic introduction of motion-pictures (movies) into Canadian agricultural and horticultural education—films of orcharding, vegetable growing, seed production, as well as purely agricultural subjects were shown at rural centres, and appear to have evoked great interest.

Disease Resistance.—Progress continues to be made in America in isolating disease-resistant strains of plants of economic importance. According to information contained in the *American Journal of Botany* (June, 1918), Asparagus-growing, which at one time bid fair, owing to the ravages of Rust, to become impossible in America, is now being resumed owing to the fact that certain English varieties—chief of which is Reading Giant—have proved to be rust-resistant. More important from the point of view of British growers is the statement that strains of Tomatos are being raised which are resistant to Fusarium wilt disease. Similarly, strains of Flax resistant to Fusarium lini have been produced and have made it possible to continue the cultivation of Flax in districts where this disease is prevalent.

Testimonial to Mr. C. S. Fuidge.—At the end of the present year Mr. C. S. FUIDGE will have completed 50 years of official connection with the Southampton Royal Horticultural Society, and it has been decided to recognise his valuable services during that long period by presenting him with a testimonial at the annual meeting of the Society in January next. The promoters of the testimonial believe many exhibitors at the Southampton Shows and also at the Horticultural Section of the Royal Counties Agricultural Shows, superintended by Mr. FUIDGE, will desire to show their appreciation of Mr. FUIDGE's services by sending contributions to Mr. J. T. ROBB, J.P., Hon. Secretary, Fuidge Testimonial Fund, 54, Inkerman Road, Woolston, Southampton.

Fertiliser Supplies.—We are informed by the Food Production Department that under the distribution scheme of the Government the production and delivery of sulphate of ammonia, superphosphate, and ground basic slag for the five months ending October 31 was 30 per cent. higher than during the corresponding period of last year.

Sale of Allotment Produce.—A rumour appears to be current in various parts of the country to the effect that allotment holders are prohibited from selling the surplus produce of their land unless they have obtained a retailer's licence. The Food Production Department has issued an assurance that this rumour is entirely without

foundation. No order compelling allotment holders to obtain a retailer's licence has been made by the Ministry of Food, nor does that body propose to make any such order. Allotment holders are perfectly at liberty to dispose of their produce in any way that they deem advisable.

Sale of Nursery Stock for War Relief Funds.—Having decided to establish a seed-testing station at Maxwellheugh, and to devote their land to the raising of pedigree stocks of farm and garden seeds, Messrs. LANG AND MATHER, of Kelso, offered the whole of their nursery stock as a free gift to the Border Union Agricultural Society on behalf of the Edenhall Hostel for Limbless Soldiers, the Newton Don Red Cross Hospital, and the Fund for Providing Comforts for the King's Own Scottish Borderers Regiment Prisoners of War Fund. This generous offer was accepted, and at the recent sale by auction, opened by Sir GEORGE DOUGLAS, Bart., a sum of upwards of £500 was realised.

Land Reclamation.—The War Cabinet has asked the Board of Agriculture to obtain information as to the possibility of carrying out schemes of land reclamation in various parts of the country if supplies of soldier labour should be available for this purpose during the period of demobilisation. The Food Production Department has circularised the Agricultural Committees of the counties on the subject. The demands of the farmers for labour required on their farms will be fully met before any soldiers are started on reclamation schemes. After the ordinary requirements of the farms have been met it is proposed that any waterlogged areas should first receive attention. Only when both these matters have been dealt with in a satisfactory manner is it intended to take up general reclamation schemes. "It is possible, however," according to the official circular, "that the normal demands of the farms and the treatment of waterlogged areas may not absorb all the labour that will be available, and, if so, it could usefully be employed in reclaiming areas which at present are uncultivated and are producing nothing. County Committees are asked to furnish at once particulars of any areas exceeding 25 acres at present uncultivated which could be brought into cultivation if labour and funds were available for the purpose. Land which is above 800 feet in altitude should not be included, and any areas which might be reclaimed from the sea should also be reported. Individuals with knowledge of areas suitable for reclamation may be doing a useful public service by writing to the Food Production Department, 72, Victoria Street, S.W. 1, giving details. It may be added that during the past two years a considerable number of minor reclamation schemes have been carried out by County Committees or private owners, and that there is no doubt whatever as to the remunerative nature of such enterprises where the area is well chosen and the scheme is intelligently directed and adequately financed. Some fine crops of Potatos grown in England this year were produced by land which as recently as February last was rough heath covered with brushwood.

Mr. W. A. Cook. We understand that Mr. W. A. COOK is shortly leaving Abbots Wood, owing to the death of his employer, the Hon. ARTHUR IAN DAVEY, who, it will be remembered, was one of the victims of the "Leinster" disaster. Both Mr. and Mrs. DAVEY were keenly interested in gardening, and under Mr. COOK's supervision many new features were added to the gardens at Abbots Wood. Mr. COOK, who was formerly gardener to Sir EDMUND LODER, Leonardslee, has an extensive knowledge of the cultivation of trees and shrubs and a wide experience in gardening generally, as his useful notes published from time to time in these pages testify. We trust that he will soon find fresh scope for his acknowledged abilities as a gardener.

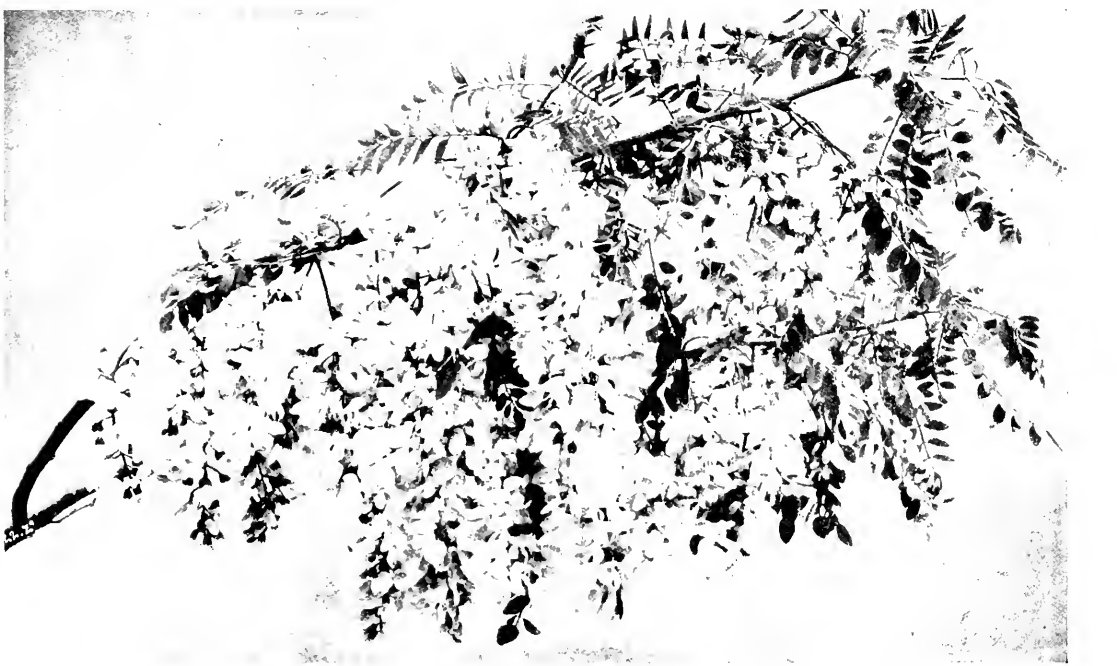

FIG. 86.—ROBINIA PSEUDACACIA VAR. COLUTEOIDES.

Photograph by E. J. Wallis.

Robinia Pseudacacia var. coluteoides. Many varieties of the Locust or false Acacia are in cultivation, and they differ in habit of growth, leaf and flower. The variety coluteoides, illustrated in fig. 86, is one of the most distinct and desirable. The tree-flowering character of the plant is remarkable. When the spray illustrated was photographed in June the whole tree, some 20 feet in height, was literally weighed down with enormous quantities of blossoms. As the varietal name coluteoides implies, the foliage, racemes, and individual flowers are smaller than those of the type. The tree under notice was obtained from Spaeth's nursery in 1905, and is one of the most distinct and desirable of a large number of Continental varieties of this native of the Eastern United States. In the last available catalogue of this firm, 1914, upwards of sixty varieties are listed. The usual method of propagating the varieties is to graft them on small plants in pots, on the roots of R. Pseudacacia, the common Locust. This is best done in spring in propagating cases, in a moderately warm pit.

British Carnation Society.—The annual general meeting of the British Carnation Society will be held at the offices of the British Florists' Federation, 35, Wellington Street, Covent Garden, W.C., on Tuesday, December 3, at 3 p.m.

Development of Afforestation in the United Kingdom. The business of making preliminary arrangements for developing afforestation in the United Kingdom has been placed in the hands of an Interim Forest Authority which has 1, Whitehall, S.W. 1, as its temporary address. The chairman is Mr. F. D. ACLAND, and the other members are Lord CLINTON, Lord LOVAT, Major D. DAVIES, Col. W. STEUART-FOTHRINGHAM, Mr. T. B. PONSONBY, Mr. A. MACCULLUM SCOTT and Mr. R. L. ROBINSON.

War Items.—We regret to learn that Lance Sergt. P. R. CATCHPOLL was recently killed in action in France. He was the youngest son of a large family living in Hampton, and at the early age of 17 years patriotically enlisted

in the York and Lancaster Regiment. He had been at the Front 3½ years, and was only 21 years old at the time of his death. Before enlisting he was employed in the nursery of Mr. VICTOR, Marling Park, Hampton Hill. In an army of brave men he was conspicuous for exceptional daring and gallantry. He had been wounded three times; he won the Military Medal in 1917, and was recommended for the Distinguished Conduct Medal just before his death.

—— Lance-Corpl. H. CATCHPOLE, Middlesex Regiment, an elder brother of the above, has also made the supreme sacrifice for his country. He died at Berrington War Hospital, Shrewsbury, from wounds received in action in France, and was buried with military honours at Teddington, where his widow and three young children reside. He enlisted in 1915, and had been wounded four times and was once gassed. Before enlisting he was employed at Mr. LENIENT'S nursery, Hampton. Both brothers were greatly esteemed in the Hampton neighbourhood.

ON INCREASED FOOD PRODUCTION.

MUNICIPAL PRIZES FOR ALLOTMENTS.

DUMFRIES Town Council has voted the sum of £10 for prizes for allotment gardens. This is expected to be an annual grant, and comes out of the "Common Good" of the burgh. Unfortunately not all Scottish Town Councils have a "Common Good" from which to defray such grants.

SUNFLOWERS IN WASTE GROUND.

So far as can be learned by local enquiry the experiment of growing Sunflowers for seed was not a success in 1918. The damp season was all against the ripening of the seed, and the yield, instead of being 12 or more cwts. to the acre, as it is said to be in Germany, reached—at all events in those cases which have come under notice—not more than half that amount. The smallness of yield is to be attributed in part to the unfavourable season and in part to the fact that every garden pest of the larger sort, birds and squirrels in particular, took large toll of the ripening seed. Much of the seed sown, moreover, proved by no means uniform, some of it throwing branching plants with numerous small heads and some single-stemmed plants with one large flower-head. The growth in fairly good ground was excessive, the plants often reaching to a height of 15 feet. So far as the plots which have been inspected show, transplanted plants did no better than plants raised by sowing in the open. It would be interesting to have the experience of others who grew Sunflowers this year. *A. N.*

SEAWEED.

GARDENERS who live on or near the coast would do well in these days of great scarcity of manure to make use of seaweed. It is a source of manure supply which is greatly neglected; tons of it lie derelict on the shores round England.

Two ways of using it may be recommended. The first is to collect it when very wet and stack it in an out-of-the-way place, covering it with earth and allowing it to remain undisturbed for 8 or 12 weeks. Usually by that time it has become first-rate humus, and can be dug in freely, especially for the Cabbage crop, as it appears to control club-root to a large extent.

The second way is to mix the seaweed in a fresh, wet state with an equal quantity of hot, fermenting stable-dung, make it into a stack as before, and leave it a month before using it. This, I consider, is the best way.

The mixture of seaweed and manure seems to be an ideal fertiliser for Peas. Trenches are taken out and a good layer of the mixture put in, and covered with several inches of soil. The Peas are then sown, and experience has proved that a greatly increased crop results. *Yorkshire.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Helenium Riverton Gem.—This desirable autumn-flowering border perennial reaches a height of about 4 feet, and grows so tast as to soon form an effective mass or clump. The colour of the bloom is difficult to define, but the general effect is that of a bright orange bronze; closer inspection, however, reveals the fact that there is a wide difference in the tint of the flowers according to the length of time they have been expanded. While this Helenium is always showy when in bloom, it is particularly striking when fully exposed to the rays of the declining sun. In these conditions the entire mass of flowers appear to be lit up with a fiery suffusion, and the rich glow is perceptible for some distance. In my suburban garden in the south-west of London, where the soil is of a stiff, clayey nature, and very cold during the winter, the plant succeeds perfectly. Opinions differ, and the yellow-flowered Riverton Beauty may be by some given the first place, but Riverton Gem is my favourite. Both varieties were, I believe, raised in America. *W. T.*

The Survival of Weed Seeds.—I am interested in the experiments and observations of Winifred E. Brenchley (p. 193) in relation to the survival of weed seeds. She describes how the store of seeds in the top soil gets depleted in time owing to various circumstances, including a new surface vegetation. I have had the opportunity this year of observing that buried seeds can accumulate in uncultivated land. On a piece of grass land a scattered few plants of Spergularia rubra have been flowering and fruiting since 1882 to my knowledge. This year the land was used for the production of food, and partly dug, partly trenched. Seedlings in large numbers began to come up over a wider area than one could have expected, and by the end of September formed a close green carpet in places where hoeing had been neglected. Trifolium subterraneum had been observed as a rare plant some years ago, yet when the grass was dug down many seedlings came up over a wide area, some of them making patches a foot in diameter and flowering. Senebiera didyma was recorded on a spot close to this land in 1865, but on several occasions since then, when the surface of the ground was broken for making or mending a path, or for other purposes, seedlings of the Senebiera came up in abundance, and were plentiful this year. The seeds of the Spergularia must have been accumulating over a period of many years; Trifolium buries its seeds; but all three plants must have been scattered by a variety of ways, and taken into the soil by worms, rain, sand bees and other agents. While discussing the problems of the seeds and how they got in the old broken up pastures, Miss Brenchley seems to have taken no account of the seeds carried on the feet of domestic animals, hares, rabbits, rats, mice and birds, and buried by the natural agencies she mentions. Seeds get carried on the muddy feet of the animals I mention, also on feet and legs made wet by rain or dew when plants are shedding their seeds. Darwin gave an account of seeds carried by partridges in this way. *J. P.*

Pruning Newly-Planted Apple Trees.—The remarks by *Market Grower* on orchards are always of interest to the practical fruit grower. To my mind, his remarks, p. 157, on not pruning trees sufficiently the first few years, go to prove that it is a mistake not to prune such trees the same season as they are planted. Yet how often do we see this error committed. The pruning of the trees should follow planting as a matter of course, hence my object in drawing attention to what I look upon as a serious error in hardy fruit culture. I have many times referred to this subject, and have no hesitation in again doing so, on the plea that there are new readers who may be glad of the reminder or the information as to procedure. From experience I am convinced that trees, especially standards, grow in the near future much more robustly than those which are not cut back the same season they are planted. Trees cut back to within a few inches of their base should make more progress than others not so pruned, because the energy of the tree is concentrated in a given space, and not extended over the whole area of the unpruned tree. Trees not pruned, instead of making vigorous shoots the first or second year after planting, invariably form fruit-buds the whole length of their shoots, and that is not what is wanted, for the quicker a large branch area is formed the sooner will fruit be obtained in quantity. *E. M.*

The Origin of the Apple, Pear, and Other Fruits.—As a believer in the multiple origin of cultivated fruits, I cannot let W. W.'s unitarian heresy (see p. 175) pass without a word of protest. There is, I think, ample evidence that several species have played a part in the constitution of the Pear, and we know that in recent times Pyrus sinensis has been crossed with cultivated varieties and given such fruits as Keiffer, and Le Conte. In Apples authorities have recognised P. prunifolia, P. dasyphylla, P. acerba, and the dwarf P. paradisiaca as probable parents. In the Vine Vitis vinifera does not by any means constitute the only species concerned. V. Labrusca and a host of American species have played a part. In the Strawberry Fragaria chiloënsis, and F. virginiana have been used to give European species fresh characters of size and flavour. The Raspberry, Currant, and Gooseberry also show every sign of multiple origin. Perhaps W. W. will reply that he does not consider the above as species, but only as varieties, which leads us to the old query: What is a species? But whatever we call them, there is, I think, plenty of evidence that our fruits do not show an "unitarian" origin, but rather a multiple one. *E. A. Bunyard.*

The Gardeners' Royal Benevolent Institution.—It is to be hoped that the appeal of Sir Harry J. Veitch, page 203, on behalf of this most deserving institution will be liberally responded to, and the required amount obtained. From my own experience I can speak of the great benefits this institution has conferred upon many gardeners, when old age and illness (an ill-matched pair) has put an end to their activities. As one of these, a particularly bright feature of my life is the receipt of the quarterly cheque, even if its purchasing power is much less than it was prior to the war. It is a great pity that so many young gardeners fail to see the benefit of subscribing to this admirable institution, often in their old age to regret their apathy in this respect. Personally, I commenced to subscribe when comparatively young, with the result that I was allowed sufficient votes to ensure my election at the first attempt. Though now quite an invalid, and confined entirely to the house, I am still vigorous enough to say: "Bless such an institution that confers these benefits on us old gardeners, and bless those that have worked so hard for it for many years." *A Pensioner.*

The Loss of Clematis in Gardens.—It has been reiterated that the cause of "die back" of Clematis is due to grafting. It appears, however, equally in our experience among self-rooted plants; in fact, so badly were our "laid" plants affected that we had to give up this method of propagation. As this has also been the experience of other growers, is it not about time that this constantly repeated statement was either substantiated or withdrawn. *George Bunyard and Co., Ltd., Maidstone.*

American Blight.—All, I think, who have recently discussed means of getting rid of American Blight on Apple trees have treated the question in a manner that suggests their thoughts to have been engaged only on the manner of cleaning the trees during winter, for one cannot paint the innumerable leaves individually with a brush! In a previous communication I remarked on the condition of some of the trees here, how the foliage was seriously infested, and how it was cleared by spraying with a solution of 2 oz. of Gishurst compound to 1 gallon of water. Not only were the insects killed, but none has been seen since. I stated at the same time and in the same communication (see p. 28) that the Blight affected only a limited number of varieties, quite a number of Apples being immune. The only person who has agreed with that statement is *R. C., Wilts* (page 122), who advises as a protective measure the Australian practice of working varieties on stocks immune to the pest. All trees that are affected do not have Blight hibernating on their roots. On the contrary, Keswick Codlin, of which large num-

bers of trees are grown here, is an example of a variety which is attacked only on the roots. The stock on which these trees are worked may not be immune, but on the whole it is obvious that the question is more involved than appears on the surface. *R. P. Brotherston, Tynninghame Gardens, Prestonkirk.*

SOCIETIES.

SCOTTISH HORTICULTURAL.

NOVEMBER 5.—The monthly meeting of this Association was held on the 5th ult. Mr. Robert Fife, the president, was in the chair, and there was a good attendance.

A lecture on "Liquid Air" was delivered by Dr. Leonard Dobbin, University of Edinburgh, with experiments. After a few general remarks on the composition of the atmosphere, and on the conditions requisite for the liquefaction of gases in general, the lecturer referred to the principle of cooling a compressed gas by its own expansion, and described how the principle is effectively applied in so-called self-intensive apparatus. The construction of the vessels used for the preservation of liquid air from rapid evaporation, and the employment of similarly constructed vessels in the well-known thermos flasks were then dealt with. A number of experiments were shown in illustration of the extremely low temperatures to which objects immersed in liquid air are cooled, and of the remarkable changes in their properties resulting from this cooling. Some useful applications of liquid air were afterwards mentioned, including its employment for the production of a high vacuum by making use of the great absorptive power for gases of charcoal cooled by it, and further, the separating from it of practically pure oxygen and nitrogen. The latter of these gases is one of the requisite materials in the manufacture of certain nitrogenous fertilisers, and liquid air is one of the cheapest sources from which it can be obtained.

CROPS AND STOCK ON THE HOME FARM.

FARMING WITHOUT SHEEP.

OWING to the difficulty of obtaining artificial food for fattening lambs, the high price of hay, the partial failure of the root crop in southern counties, the shortage of manual and horse labour, and especially the low prices prevailing, I fear many of the breeding flocks of sheep are being reduced in number.

Although Hampshire Down sheep are among the best for close folding to benefit the land from a manurial point of view, and their lambs come quicker to a useful size early in the year than those of any other breed for their age, it cannot be denied that they are expensive. A flock of from 300 to 400 ewes costs about £2 600 per annum; add to this the anxiety when there is a shortage of food, bad weather at lambing time, and sundry other difficulties, the sheep are not always a reasonable financial success.

Many farmers are keeping dry sheep only in the place of a ewe flock, as these can be fattened when the requisite food is available and sent to market, while the stock can be replenished at will.

A flock of 500 ewes will consume from December 1 (or earlier, according to the weather) to April at least 150 tons of hay; this, valued at £3 per ton, means a large outlay—£1 200. Such a prospect will lead, I fear, to a diminution of sheep, much to the regret of what I term the older type of farmers, who think Corn cannot be grown successfully without sheep. This idea may be discarded at once, as I know several farmers who do not keep sheep on their arable land, but they produce Corn in abundance. When inspecting one of these farms last harvest time I was surprised to see and hear of crops of Barley growing where Barley had been grown on the same plot for four years in succession. In this connection I have another experience to relate; only last week, when threshing a 6-acre plot of Red Standard Wheat grown on soil only 4 inches to 5 inches deep over chalk, situate on the Downs, the average return was 10 sacks per acre of an excellent sample of miller's Wheat, and sheep had not been on this land for twelve years.

I refer to these instances to illustrate the possibilities of Corn production without sheep, and to encourage small holders who wish to grow Wheat and who cannot possibly keep sheep. The crop of Wheat just quoted is another instance of what despised down land is capable under reasonable tillage. This plot was originally a part of the Downs used only for sheep grazing in the summer, but it was ploughed up fifteen years ago and has produced many good crops of Corn and Potatos since.

EXTENSION OF ARABLE LAND.

I am pleased to learn that the Food Production Department intends to increase and improve the arable land in the country with a view to obtaining greater yields of cereals and other foodstuffs. The more arable land there is under good cultivation the greater is the prospect of the nation becoming self-supporting. I am still more pleased to hear this Department intends to enforce the better cultivation of badly managed arable land.

The Advisory Committee for our area of 37 000 acres has instructions to survey all farms with a view to increasing the arable land where advisable, and I hope it will also suggest the improvement of existing pasture land, which in so many instances could produce heavier crops of grass or hay for milk production. Too many persons are content with half a ton of hay per acre without any outlay in manure or labour. Nothing less than double that quantity should satisfy anyone. No doubt the Department will be prepared to assist deserving cases, as this would be beneficial to the nation.

With a reduction in the price of fertilisers and more skilled labour available, I am looking forward to greater activity in the cultivation of the land, and especially to the increase of small holdings which have in the past three years given a high yield of desirable produce. Now that the public realises the great value of vegetables and fruit as food there should be a great stimulus to the small holding industry.

LOCAL MARKETS.

The establishment of local markets under the auspices of the Food Production Department for the sale of surplus vegetables, fruit, flowers, poultry, eggs and butter will give a great impetus to cultivation and considerably add to the food of the nation. The idea is to arrange for a public auction (already in existence in many counties) about twice weekly in a convenient part of a town where the consumer can be brought into direct touch with the producer without the aid of the middleman. In rural districts cottagers, gardeners and allotment holders would grow much more produce if they could dispose of it readily at a reasonable price, and thus receive a due reward for their labour.

For this purpose Hampshire is divided into three areas, and for one of these areas I am a member of the committee detailed to arrange a scheme. The most difficult problems are the necessary buildings and the transport of the produce. The idea is to collect produce at various centres and convey it by motor to the market hall, where it would be sold by public auction. A small collecting and selling fee would be charged. Such a scheme would also tend to benefit the town dwellers in various ways.

Two such markets are established in Bournemouth, and are a success from all points of view.—*E. Molyneux.*

MANURES.*

As a general rule Wheat grown after Potatos, Mangolds or Clover will need no artificial manures. Exceptions arise where the crop does not suitably start growth quickly or ripen sufficiently early; in these cases superphosphate or basic slag should be applied at 1½ to 2 cwt. of superphosphate or 3 to 4 cwt. of basic slag might be given, and it should be applied at the time of sowing the seed. The heavy dressings of basic slag used in some parts of the Eastern and Midland counties should only be given where there is sound reason to suppose them necessary.

* "Notes on Manures in November." From the Rothamsted Experimental Station, Harpenden, Herts.

Barley grown after roots which have been fed to sheep on the land may need superphosphate if there is reason to fear that the crop will become lodged. In present circumstances 1½ cwt. to 2 cwt. per acre might be allowed to obviate this trouble.

Oats may repay rather more generous treatment, and if they are receiving no dung may have ¾ to 1½ cwt. sulphate of ammonia, 3 cwt. of superphosphate, and if the soil is light 2 cwt. salt per acre.

Corn crops following a previous corn crop will also require liberal treatment: ¾ to 1½ cwt. sulphate of ammonia according to the condition of the land, 2 to 3 cwt. superphosphate, or double this quantity of slag, and on light or chalky soils 2 to 3 cwt. of salt. Some farmers would be inclined to use more; in a case recently brought to the notice of the Rothamsted Experimental Station the farmer was proposing to add 2 cwt. of bone-meal to this mixture, but the addition could not be recommended, as there was already sufficient plant food for the needs of the crop.

Roots require very careful consideration. In many parts of the country it is customary to use dung and, in addition, heavy dressings of artificials. For Swedes and Turnips this plan cannot as a rule be recommended. Large numbers of experiments have shown that Swedes and Turnips do not generally respond to these heavy dressings, and equally good results have been obtained with smaller applications. Unless, therefore, a farmer has very definite evidence that the artificials will really give a useful return he should not use them too liberally. The practice of giving a small dressing of superphosphate to "bring the roots to the hoe" is, of course, justifiable. One half cwt. of sulphate of ammonia and 3 cwt. of superphosphate might be allowed, but no one should apply the 8 or 10 cwt. per acre of artificials sometimes used in addition to farmyard manure, unless he has very good reason to expect an adequate return.

Mangolds present rather a different case as they more definitely respond to fertilisers than Swedes or Turnips; indeed no crop is grown that responds so clearly. In most cases it is advantageous to supply a complete dressing; a useful one would be 1 to 1½ cwt. of sulphate of ammonia, 2½ cwt. of superphosphate, and 2½ cwt. of salt per acre in addition to dung.

Potatos also respond to dressings of artificial fertilisers, though it is by no means clear that they justify the heavy dressings sometimes given. In Potato-growing districts it is not unusual to apply 10 cwt. of artificials. In peace time, or when there is an abundance of fertilisers, there is not much to be said against this plan, and the possibility of increased crops may justify it; but in war-time, when fertilisers are scarce, it becomes absolutely necessary to economise, and large dressings should not be given unless there is definite evidence that they are needed by the crop.

TRADE NOTES.

NURSERY WORKERS' CLUB.

STEPS have been taken to form a social and recreation club for workers in nursery and market gardens in the Hampton, Middlesex, district. There are several hundreds of such gardens in and around Hampton, employing a large number of workers. A provisional committee has been formed with Mr. J. Quarntrill as chairman, Mr. R. O'Callaghan vice-chairman, Mr. F. J. Cane treasurer, and Mr. F. White as secretary, and an appeal is being made for funds to "equip and maintain the club, which has been instituted with the object of providing opportunities for reasonable recreation, of social intercourse, and of mental and physical development." It is hoped to make a useful, up-to-date club fitted for billiards and other indoor games, with reading room and library, and to institute "sub clubs" for cricket, swimming, etc. The club is to be entirely non-sectarian and non-political, and the committee will make every endeavour to enlist the sympathy and co-operation of the employers. There is a special desire to make life more pleasant and happy for the hundreds of nursery hands who are soon expected back from the various theatres of war.

REMARKS.—The supplies and prices of flowers show little change from those of last week. Roses are becoming fewer, and prices are advancing, especially for good red sorts. A limited number of Poinsettias are now being offered in excellent condition. Small consignments are arriving from Guernsey, consisting chiefly of yellow Soleil d'Or and paper white Narcissi, and Violets. Smilax is also arriving from this quarter in larger quantities. A few pads of paper-white Narcissus and Parma Violets arrived from France last week in fairly good condition; 10d. and 1s. per bunch being realised for Paper-Whites. A few Roman Hyacinths, on bulbs, were offered for sale this week. Camellias are now offered for sale in boxes, consisting of 12 to 18 blooms, according to size.

Fruit: Average Wholesale Prices.

REMARKS.—Supplies of Muscat Grapes are limited, but Gros Colmar and Alicante are fairly plentiful, while Almerias are offered in barrels containing about 42lbs. of dessert Apples a few good Cox's Orange Pippins reach the market; cooking varieties consist of Wellington (Dumelow's Seedling) Bramley's Seedling, Newton Wonder, Dr Harvey, and a few others. French Asparagus is coming in, but Tomatos and Cucumbers are both in limited supply, while Dwarf Beans are not so plentiful this week. Green vegetables are fairly plentiful for the time of year.—*E. H. R., Covent Garden Market, November 27, 1918.*

ANSWERS TO CORRESPONDENTS.

AMERICAN GREASE FOR GREASE-BANDING FRUIT TREES: *P. H.* For supplies of American grease for grease-banding fruit trees without the use of paper, application should be made to the horticultural sundriesmen whose names and addresses are to be found in our advertisement columns.

DICTIONARY OF BOTANICAL AND HORTICULTURAL TERMS IN VARIOUS LANGUAGES: *A. G. N.* In 1894 a dictionary of the principal terms employed in botany and horticulture, set out in the Latin, French, English, German, and Dutch languages, by "A. M. C. Jongkindt Coinck, Horticulteur, à Bussum, près d'Amsterdam (Pays Bas)," was published in Haarlem by Les Héritiers Loosjes, in Antwerp by La Librairie Néerlandaise, and in London, Paris, and Leipsic by La Libraire Nilsson.

DISEASED CALANTHE PSEUDO-BULBS: *L. D.* Calanthes are very liable to physiological disorder if the temperature of the house in which the plants are grown falls low during the period just previous to the completion of the pseudo-bulbs. In such conditions the pseudo-bulbs become spotted, and sometimes have considerable areas of blackened or dull grey tissue that denote bad health. Low temperature is the chief cause of this trouble, but the pseudo-bulbs may become similarly affected if liquid manure is used at too great a strength, whilst if an excess of water is applied to the roots concurrently with a low temperature the trouble is greatly aggravated.

HARDY PERENNIAL FLOWERS FOR LARGE BEDS: *J. R.* Kniphofias are excellent subjects for planting with Yuccas, such as Y. recurva and Y. flaccida. A few of the best Kniphofias are Saundersii, orange-scarlet; Burchellii, orange-scarlet; Lachesis, dark yellow; Obelisque, chrome-yellow; and Lemon Queen. Of smaller-growing species K. rufa is one of the best flowering, as it blooms all the season. Sedum spectabile makes a fine bed for autumn, and a spring display is assured by interplanting with a Narcissus such as Emperor or Empress. Another effective bed may be had by planting Achillea filipendulina, with Trollius (Globe flower) for a spring display. A large bed of Nepeta Mussinii planted with Darwin Tulips, such as Clara Butt, is very effective when the plants are in bloom. The Nepeta is also very suitable for planting with Lilium longiflorum; the chief objection to this combination is the fact that the Lilium needs to be renewed every year, but Lilium testaceum might be used instead. A large bed of Nepeta and the common pink Monthly Rose is always much admired, or there is a variety of the Monthly Rose called Hermora which might be used. Monthly Roses interplanted with Lavender are pleasing all through the season, especially if Lilium candidum is grouped with them. Anemone japonica alba var. Whirlwind and Lilium Hansonii make a useful bed, while the Rose-coloured Anemone Queen Charlotte might be planted with Hyacinthus candicans. This Hyacinthus is useful for planting with a number of hardy herbaceous plants; it gives a good succession interplanted with Delphiniums or Anchusa italica var. Dropmore. It can also be used with herbaceous Paeonies, and with them Narcissi can also be used; they are very effective with the bright-coloured young growths of the Paeonies. Thus one may have three distinct floral displays from one bed, and all hardy plants. Gladioli may be used instead of Hyacinthus. A very large bed can be rendered effective by planting Salvia virgata, with an edging of Santolina Chamaecyparissus (Lavender Cotton), or the smaller Santolina incana may be used. Salvia virgata interplanted or edged with Artemisia ludoviciana var. guaphaloides also proves very effective. Cerastium tomentosum can also be used. Another combination which gives a lasting display is Eryngium planum and Campanula persicifolia, or Campanula carpatica may be used in the same way. Campanula persicifolia var. alba could be interplanted with Geum Mrs Bradshaw, or a good variety of Chrysanthemum maximum might be used instead. The beautiful white Phlox, F. A. Buchner, with a groundwork of Potentilla Gibson's Scarlet, makes a good bed, or Geum Mrs. Bradshaw might be substituted for the Potentilla. Erigeron Quakeress, lavender-blue, and E. B. Ladhams, pink, are two splendid border plants which flower all the season. Some of the strong-growing Phloxes could be used; Iris and Le Mahdi, of bluish-violet colouring, are best grouped with white flowers, in a partially shaded position. In furnishing beds of this character more frequent use should be made of hardy herbaceous plants with large, handsome foliage. Acanthus mollis, A. latifolius, A. spinosus, and Bocconia cordata have imposing foliage, while all the Funkias can be used with good effect, either alone or as edgings to beds of taller-growing plants. The large-leaved Saxifraga cordifolia is another plant suitable for the same purpose. For a spring display plant Anemone apennina, Muscaries, Scillas, and Chionodoxas, which die down and take no harm when overplanted later in the season.

INSECTS ON PEAR TREE: *C. G.* The insects are "Beetle Mites" (Oribatidae). They eat the green algae, moss, and other foreign growth on the bark, and are thus beneficial. The Pear tree would be benefited by the application of a caustic winter wash.

NAMES OF FRUITS: *T. E. T.* 1, Winter Hawthornden; 2, Round Winter Nonsuch; 3, Hormead Pearmain; 4, Gascoyne's Scarlet; 5, Wealthy; 6, Calville St Sauveur; 7, Flanders Pippin; 8, Egremont Russet.—*R. B. Hessle, S. W. W.* 1, New Bess Pool; 2, King of the Pippins.—*G. E.* (a) Radford Beauty, (b) not recognised, (c) Cockle Pippin.—*C. C. P.* Lady Henniker.—*L. C.* 1, King of the Pippins; 2, Tower of Glammis; 3, Mère de Ménage; 4, Hanwell Souring; 5, Emperor Alexander; 6, decayed, not recognisable; 7, Marie Louise.—*C. H.* The Apple is evidently a seedling, and probably has no name; the specimens received were very poor, both in size and quality, and if they are representative fruits the variety is not worth growing or naming.—*T. S. and Son* 1, Annie Elizabeth; 2, Baumann's Red Winter Reinette.—*J. O.* Apple not recognised.—*D. W.* Hambledon Deux Ans.—*J. H. J.* Gascoyne's Seedling.

NAMES OF PLANTS: *G. E.* Gazania rigens.—*F. E. W.* 1, Cycas revoluta; 2, Lomaria spicant; 3, Sempervivum arachnoideum.—*C. H.* 1, Justicia carnea; 2, Pyrus Aria; 3, Phormium tenax; 4, Leycesteria formosa; 5, Peperomia marmorata.—*C. I. W. Bucks.* 1, Pieris japonica var. variegata; 2, Skimmia Laureola; 3, Euonymus radicans var. Carrièrei; 4, Cupressus pisifera var. plumosa albo-variegata; 5, Cedrus atlantica var. glauca; 6, Elaeagnus pungens var. Simonii.—*T. J., Portobello* There are no features in the flower of Odontoglossum sent to distinguish it from a blotched form of O. crispum. If it is a hybrid it may be a variety of O. eximium (crispum × ardentissimum) reverted to the O. crispum parent.

PARSNIP WITH BROWN MARKINGS: *Herring.* The primary cause of this disease is the so-called "Parsnip Canker," which is not caused by any organism, but is "physiological." Late sowing is recommended, and liming; also the application of 5-10 cwt. of salt to each acre.

RED SHALLOTS: *C. F.* The bulbs sent represent the Jersey or Giant Russian variety of Shallot. This form is easily recognisable by its coppery-red skin and the pale violet colour of the bulbs immediately underneath the outer skin. Potato Onions are quite different.

VIOLET MR D. LLOYD GEORGE: *M. E. B.* The new Violet named Mr D. Lloyd George, and illustrated on p. 199 of the *Gard. Chron.* of the 16th inst., was exhibited by Mr. J. J. Kettle, Corfe Mullen, Wimborne.

NOTES FROM KEW.—XI.*

THE best of gardens have a more or less unkempt, deshabille appearance in November. Evidences of decay and death are everywhere, and it requires a cheerful mind to find pleasure in a walk through Kew when the dead leaves are littered over the lawns and paths, and beds and borders are disfigured by withered decaying stems. Yet things are not so bad as they look, as Philander Spratt would say. The dead leaves, if allowed to lie, enrich the borders, and it is astonishing how many of them are dragged into the soil by worms unless in a spirit of tidiness the broom is kept constantly at work. It is a mistake, and worse, laboriously to remove dead leaves as fast as they fall. The wind will gather them together from the open spaces and distribute most of them among the shrubs and beds, where they will serve as protection in winter and as a mulch in summer. It is Nature's way of restoring to the soil much of what was taken out of it by the roots, and some of what was taken in from the atmosphere by the leaves when they were green and active.

The rich brown colour of dead leaves of Beech and Oak, the yellow of Maple and Poplar, and the various other shades assumed by deciduous leaves in autumn are not without charm as they lie on the lawns. Of course, they suggest the end of the year, the break up, the moult of vegetation; still, they form an important part of the scheme of plant life, and therefore need not be objected to, much less give rise to feelings of despair.

Hundreds of loads of leaves are being collected now at Kew. They are wanted for leaf mould, which is to loam, as the gardener thinks, what butter is to bread. Properly prepared, leaf mould is good food for many plants. But it must be properly prepared, or it may disagree with them. Eelworm, the most troublesome of all soil evils, is often abundant in leaf-mould. At Kew, nowadays, no soil is safe, for pot plants at any rate, until it has been sterilised by steaming—a laborious operation, but necessary if the plants are to grow satisfactorily. Steaming for eelworm and sulphur-vapouring for mite were unknown forty years ago. These two pests have come among us as silver leaf and American blight have. There is need of a simple machine for soil sterilising, for it looks as though one will be as necessary in the garden as a lawn mower is.

Leaf-mould, finely sifted and mixed with sand, is used at Kew as a winter dressing for the plants in the rock garden. The old soil is loosened with a hand-fork, and half an inch or so of this mixture is spread. We cannot provide a covering of snow, which the plants get in the mountains in winter, so light leaf-mould serves as a substitute. Rain, fog, and frost have stopped growth and cut off the foliage of many things. Only two Alpines have held on—the lovely Gentiana sino-ornata, one of the very best of the many herbaceous plants recently introduced from China, and Primula capitata. These two were boldly in flower in mid November, after holding out against several frosty nights. The only plant in flower in the herbaceous garden is Helleborus caucasicus (viridis), which is green flowered and not showy.

On the walls the ever welcome yellow Jasminum nudiflorum and the fragrant Lonicera Standishii (see fig. 89) are the only two plants in flower. Berberis Wilsonae promises to be as useful as a berry plant for Christmas decorations as Holly is. For all practical purposes B. Stapfiana and B. subcaulialata may be considered seedling varieties of B. Wilsonae, which is evidently a variable plant. Someone has suggested that it is a natural hybrid, as its seedlings vary so. Be that as it may, B. Wilsonae is a most decorative hardy shrub, its great time being early winter, provided the birds do not strip it of its bright scarlet berries. Next to it in value as a berry plant is our own B. vulgaris, neglected of gardeners, yet a champion shrub. A month ago it was the most attractive of all Barberris in the Dell at Kew.

There is beauty in the stems of some plants in winter. We all love the Birches, two of the best of which are the American red Birch, Betula nigra, and the Japanese B. Ermanii, the former with shaggy stems, owing to the brown bark hanging in large, loose flakes, and the latter silvery barked. Both trees are of elegant habit. The shiny black twigs and small branches of Birches are effective when they are leafless. Sargent says the bark of Birches is impervious to water, hence its use for roofing and for shoes, canoes, and boxes.

The red and yellow barked Willows are well known, and so are the white stemmed Brambles, Rubus leucodermis, R. coreanus, R. tibetanus, R. biflorus, and R. Veitchianus. To these may be added, on account of its shining crimson stems, R. No. 11, which Kew obtained from Mr. J. C. Williams. It is, no doubt, Chinese, yet it differs from all other Chinese brambles in its pinnate, rugose leaves, which are silvery on the under side, and in the character of its sturdy stems, which are about 6 feet long, suberect, and very spinous. Another of Mr. Williams' gifts to Kew is an Acer, said to grow 50 to 60 feet high, with cordate leaves, red petioles, and the trunk and main branches brown purple, prettily reticulated with white.

If someone would introduce a new tree—it might be as large and noble as the Douglas Fir—there is a good name waiting for it—Georgia Wilsoniana,* and it could be planted throughout the country to commemorate the end of the world's war and the services of the two great leaders. An avenue of it might be made at Kew, where one ought to have been made of Wellingtonia. Writing of avenues, that of the Irish Yew, near the Pagoda (see fig. 90) has not grown appreciably in the last forty years. Peter Pan like, the Irish Yew will never grow up. Ilex verticillata, the American Winterberry, is a good garden shrub, as it has showy bright red berries, which hang on after the leaves fall in autumn. It grows about 6 feet high, and is of spreading, rather close habit. Pyracantha Gibbsii, recently awarded the R.H.S. First Class Certificate, is surely P. crenulata. Mention should be made of the Spindle trees, which this year have fruited exceptionally well; but the birds soon spoil them, as they do the Pyracanthas, and, indeed, all berry bearers at Kew. It is worth while, perhaps, to have a bird sanctuary, which Kew proudly is, but the birds exact a heavy toll. Numbers of jays and of the lovely green woodpecker are now to be seen in the neighbourhood of the lake, where the geese are.

In the plant houses there is not much that is noteworthy. No. 1 is bright with Chrysanthemums, Begonias, a beautiful lot of the winter flowering race of Veitchian origin; Jacobinia chrysostephana, with orange and yellow heads of flowers, suggestive of Chrysanthemums; Calceolaria Burbidgei, a first rate pot shrub for winter flowering; Eustoma Russelliana, Columnea magnifica, Tibouchina semidecandra, Heeria rosea, Abutilon insigne, and a large selection of the more familiar winter flowering plants.

Diospyros Kaki, in No. 5, is carrying a good crop of big, Tomato-like fruits which will hang on the tree till about March. For a wonder there is not an Agave in flower at Kew. Solandra grandiflora, a big climber which sprawls over the tree Euphorbias, is well budded, and will give a show of large yellow trumpets about Christmas. In the Orchid houses Cymbidium Traceyanum is a great attraction owing to its powerful Vanilla-like fragrance as much as to floral beauty. What is the origin of this fine Orchid? The suggestion has been made that it is a natural hybrid between C. giganteum and

* Previous articles appeared in the issues of January 19, February 9, March 9, April 6, May 18, June 8, July 6, August 10, September 21, and November 2.

* Dahlia has been called Georgia.—Eds.

C. grandiflorum. The cross might be made artificially if this has not already been done. Hooker did not recognise the plant as a species in his *Flora of British India*. It first appeared in 1890 among a batch of imported C. Lowianum in the nursery of the late Mr. H. A. Tracey, at Twickenham. There is a good show of Cattleya bloom, a poor one of Odontoglossum, and a fair one of Cypripedium, the largest of which is Ypres and the prettiest San Actaeus. The Queen Laelia anceps and its allies are fast coming into flower, and there will soon be a grand lot of Calanthes, the plants having grown exceptionally well this year. Arachnanthe Clarkei is in flower.

Is Orchid spot amenable to any known treatment? The late George Mussee, who examined many diseased Orchids, maintained that spot was due to defective cultural conditions. "It does not require the attention of a plant pathologist, but of a careful gardener, who has some sense of proportion with respect to heat and moisture. For spot is due to either too high a temperature, too much water, bad ventilation, or watering or spraying at the wrong time." When a well-known clever cultivator, who had a visitation of spot among his Orchids, was told this, he retorted that "such information is absolutely and utterly valueless to growers who ask for help from science. My treatment of Orchids is well known, and those who say it is defective had better come and see them and point out what is wrong." The disease comes and goes mysteriously. It is a great deal too much in evidence at Kew now, and there are other collections in the country that are afflicted in the same way. The late Professor Marshall Ward maintained that the disease was "certainly not fungoid," and Mr. W. B. Brierley, who recently examined a number of spot diseased Orchids, said "the blotches are not due to any pathogenic organism but to the deposition in the cells of an indigo-like body, and the subsequent death of the immediate tissues." This suggests poisoning, probably atmospheric, for which preventive measures are not easily devised. The trouble appears to be most frequent in collections in or near large towns. Certainly many plants at Kew suffer from atmospheric poisoning. Odontoglossums and Pelargoniums notoriously do, and the Rhododendrons make comparatively undersized leaves, probably for the same reason. It is easy to say treat the plants better, but as the irate correspondent mentioned above replied, in what respect is the treatment wrong? W. W.

FIG. 89.—LONICERA STANDISHII: FLOWERS CREAMY WHITE.
(See p. 223.)

ORCHID NOTES AND GLEANINGS.

NEW HYBRIDS.

BRASSO-CATTLEYA PEARL.—A flower of this delicately-tinted cross between B.-C. Digbyano-Schroderae alba and C. intermedia alba is sent by Frederick J. Hanbury, Esq., Brockhurst, East Grinstead. The lanceolate sepals and petals are white tinged with lavender colour. The lip also is white with lavender-tinted front, which is lightly veined with rose colour.

LAELIO-CATTLEYA RUFUS.—This hybrid between C. Dowiana aurea and L.-C. Amazone (L. purpurata × C. maxima) is also sent by Mr. Hanbury. It is a showy cross, notwithstanding that the sepals and petals are narrow. Their colour is apricot-yellow tinged with rose. The lip, which in the tubular arrangement of the base discloses C. maxima, is well expanded and crimped at the margin: the centre is reddish crimson changing to violet towards the margin. The base has a series of closely-arranged thin gold lines.

SOPHRO-CATTLEYA GWENDOLINE.—We have received a flower of this variety from J. Ansaldo, Esq., Rosebank, Mumbles. It was raised between Cattleya Octave Doin (Dowiana aurea × Mendelii) and S.-C. Wellesleyae (S. grandiflora × C. labiata). The flower is the first to develop, and the mature plant should prove a pretty and distinct hybrid. The segments are of good substance and coloured light yellow; the lip, which has a cherry-red band in front, is darker than the other segments.

CYPRIPEDIUM PEACE.

A FLOWER of this pretty and new hybrid between C. Psyche (bellatulum × niveum) and C. Lathamianum (Spicerianum × villosum) is sent by Mr. F. C. Puddle, gardener to W. H. St. Quintin, Esq., Scampston Hall, Rillington, Yorkshire, whose efforts in crossing C. niveum have added to our collection many pretty hybrids with C. niveum features, but enlarged in size.

The present variety adheres closely to C. Psyche in its pure white ground and effective display of numerous, closely-arranged violet spots on the upper sepals and petals. In the form of the flower, the upper sepal of which is 2 inches wide, and petals 1⅞ inch across, C. bellatulum is strongly in evidence. C. Lathamianum—which was raised by Mr. W. B. Latham, at the Botanic Garden, Birmingham, and first flowered as long ago as the spring of 1888—is difficult to trace in it except in the form of the lip, which has a pallid, yellowish tint. The connate lower sepals are strongly concave, forming a shallow cup behind the lip, white, and unusually large for flowers of this class.

SOME OF THE NEWER ROSES.

(*Continued from p.* 214).

ROSES INTRODUCED IN 1914.

CANDEUR LYONNAISE (Croibier).—A very fine white Hybrid Perpetual Rose, in the way of Snow Queen, but larger, fuller, and more globular; a strong grower and hardy.

The following are Hybrid Teas:—

AUGUSTUS HARTMANN (B. R. Cant).—One of the best Roses in existence. A bright Geranium-red; fine shape and petal, full, holds its head up well, and at its best is a marvellous colour. Large and free. My favourite among red Roses.

AUTUMN TINTS (B. R. Cant).—A lovely combination of orange-copper and red, very free; of medium size and a fine bedder.

BRILLIANT (Hugh Dickson).—A Rose of wonderful colour; brilliant scarlet; occasionally full, but usually only fairly full. It has not grown well here as a dwarf, but I have only had it one season, budded on half-standards. In one nursery I saw an astonishingly fine bloom of it.

COLLEEN (McGredy).—This has beautiful rose-coloured blooms, of a distinct shade, on a yellowish ground; full and pointed; a good Rose and a fair grower.

COUNTESS CLANWILLIAM (Hugh Dickson).—No Rose in my garden receives more admiration than this. It is described as peach-pink shaded and edged with cherry red, and so it often is. I have had it with a yellow base rather than peach, and a friend and I discuss which form is the more beautiful. Of fair size, lovely shape, fairly full, a fair grower, and most fascinating.

EDGAR M. BURNETT (McGredy).—A full, large Rose, rather of the La France colouring; good grower, free, and suitable either for show or garden purposes.

FLORENCE FORRESTER (McGredy).—A grand flower, with a slight lemon tinge that fades to pure white; large, very full, and free. Its fault is that it is rather a stumpy grower, and so free flowering it can hardly manage to make enough growth.

H. V. MACHIN (Alex. Dickson).—Another grand Rose, with a stumpy habit of growth. The bloom is scarlet-crimson, shaded black; very large and very full. Unsurpassed for exhibition. It holds up its heavy blooms perfectly. Would that it were a better grower!

IONA HERDMAN (McGredy).—A lovely orange-coloured garden Rose, but though free it does not do well everywhere. It may prove hardier and more vigorous with time.

KILLARNEY BRILLIANT (Alex. Dickson).—A richer and deeper Killarney, and here not so subject to mildew so far. The colour at its best is very striking; free and vigorous.

MAJESTIC (W. Paul).—A fine, large Rose, carmine-rose; fairly full, and suited either for bedding or show purposes.

MRS. AMBROSE RICARDO (McGredy).—One of my favourites; a lovely Rose, full, opens well, and has blooms of great size; honey-yellow in colour and in style suggesting Mrs. Vanderbilt, but of different colour. Vigorous and free. Strongly recommended.

MRS. ARCHIE GRAY (Hugh Dickson).—A good pale yellow variety, of fine size and shape, and fairly full. A charming Rose.

MRS. CHARLES REED (Hicks).—Another good pale yellow variety, a good garden Rose, and occasionally up to show form.

MRS. CHARLES RUSSELL (Wahan Conservatories).—A very fine Rose; rosy-carmine with a red centre; full, and a good grower, but the colour goes wrong in some weather conditions. Grandly shown in many stands two years ago.

MRS. GEORGE NORWOOD (Hicks).—A very fine pink Rose, of good size and fine shape, full, free, and very good. Its fault is that it is among the rather stumpy growers.

MRS. JAMES LYNAS (H. Dickson).—Another fine Rose, in the style of Pharisäer and Ethel

Malcolm. In growth probably between the two; fine in size and shape, fairly full, and very delicate in colour.

MRS. WEMYSS QUIN (A. Dickson).—Quite one of the best of the new yellow Roses, a fairly strong grower, deep rich orange yellow in colour; free from mildew, and a most useful garden variety.

NAARDEN (Van Rasen).—A good and nearly white Rose, tinged towards the centre; large and free, but hardly distinct enough, as we have many more or less similar.

RED LETTER DAY (A. Dickson).—A finely coloured and all but single Rose; rich crimson, a good grower, free, and among the best of its class.

WILLIAM COOPER (H. Dickson).—A lake red; large, free, fair in shape, and moderately full. Good in autumn, and a good garden Rose.

OTHER ROSES OF 1914

LADY PLYMOUTH (A. Dickson).—An all-round fine Rose, and really good; large, of fine shape, pale yellow, and a quite good grower. One of the best of modern Teas.

MRS. CAMPBELL HALL (D. Campbell Hall and A. Dickson).—An exceptionally beautiful Tea Rose, quite distinct, and very fine in shape; a good grower on half standards, extraordinarily free; said to be delicate in some places, but so far it has not been so here. A great acquisition.

MRS. S. T. WRIGHT (A. Dickson).—A deeply coloured sport from Harry Kirk, perhaps not quite so strong a grower, and buds does not take easily when budded. It is of a lovely colour, gold, shaded inside with rose; at times it has been deep orange. I strongly recommend this Rose.

DOLLY VARDEN (G. Paul).—An interesting break, as it is a perpetual rugosa; lively salmon pink, with yellow base, good size, not very full, growth 3 feet to 4 feet, an excellent garden Rose.

SHALIMAR (Bartell).—Blush often edged with rose, a distinct and good Wichuraiana Rose, and so far as I can at present judge a quite good grower; certainly very pretty. A sport from Minnehaha.

CLIMBING MELANIE SOUPERT (Bartell).—This climbing H.T. promises to prove a great gain, as the blooms are like those of the ordinary form from which it sported, but even better.

GEISHA (Geschwind).—This I have not grown myself, but it gives promise of being one of the best scarlet-crimson climbers, with large flowers, and very free.

WHITE RAMBLER (Pemberton).—A decidedly valuable Rose, as it is consistent in colour, does not become mildewed, and has a long period of flowering.

ROSES INTRODUCED IN 1915

ANNIE CRAWFORD (D. Campbell Hall).—A fine pale pink Hybrid Perpetual; a stronger, paler Mrs. J. Laing, of upright growth, free, and decidedly good. Does not go wrong in colour as Mrs. J. Laing so often does.

LOUISE CRETTE (Chambard).—This Hybrid Perpetual Rose seems to be an improved Frau Karl Druschki, with growth more like that fine Rose Couleur Lyonnaise. I shall be much disappointed if it does not prove very nearly our best white variety.

The following are Hybrid Tea varieties:—

ADMIRAL WARD (Pernet-Ducher).—Crimson shaded purplish, large and full; rather too globular for present taste, free, and of spreading growth; fairly vigorous; good.

CHEERFUL (McGredy).—A lovely Rose, very distinct, and a great advance if it proves vigorous enough. No Rose in my garden has received more admiration from ladies than this. It is one of the "orange flame" sort, distinct in colour, full, and of fine shape. It might have greater length of petal, but it opens easily, and at once catches the eye.

EDWARD BOHANE (A. Dickson).—A fine scarlet show Rose, holding its head up well; large, of finely imbricated shape, free and vigorous.

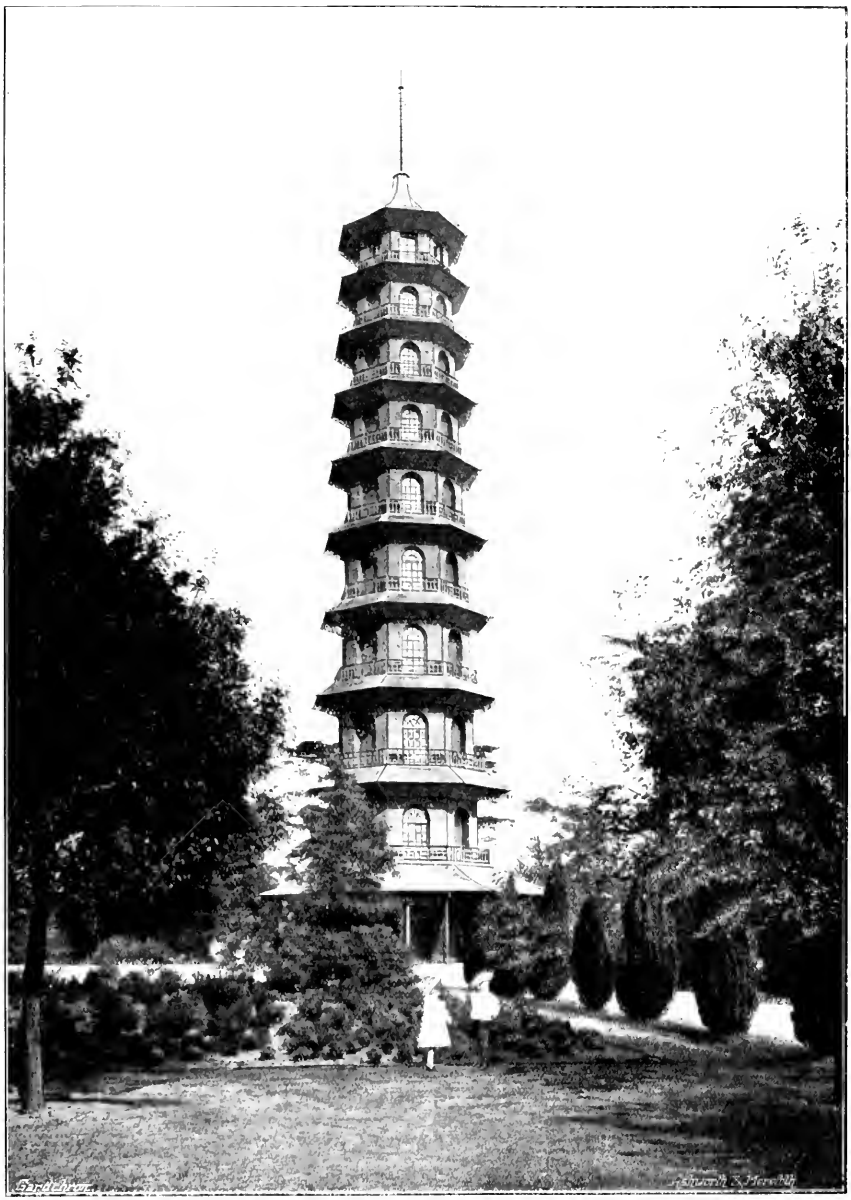

FIG. 90.—PAGODA IN KEW GARDENS, SHOWING THE IRISH YEWS IN THE YEW AVENUE (See p. 234).

G. AMEDEE HAMMOND (A. Dickson).—A medium grower, of fair size, and described in the N.R.S. Catalogue as apricot in colour, but with me, so far, it has not been so deep a yellow.

GOLDEN MEYER (G. Paul).—A golden sport from the well-known Edu Meyer, free, and a fine garden Rose.

HOOSIER BEAUTY (Dorner, not Hoosier B.).—A fine crimson Rose, of good shape, fairly full, and a free, good grower; its main fault seems to be its "whippy," thin wood.

GORGEOUS (H. Dickson).—This I consider one of the very finest Roses of late years, and bound to be included among the best. Its colour is orange, shaded copper; it has large, quite full blooms that open well and are of fine shape. Holds its head up, lasts well, and grows freely.

JANET (A. Dickson).—Described as a dwarf Gloire de Dijon, but this, I think, hardly does it justice. It is free, a good grower, yellow in colour, sometimes with a salmon shading, large, well formed, and holds its head up. Very thorny.

LADY BOWATER (W. Easlea).—A large, full bloom, white, sometimes shaded apricot; has sturdy wood, holds its head up, and is a medium grower.

MADME. COLETTE MARTINET (Pernet-Ducher).—A fine garden Rose, yellow, old gold and orange; of fair size, vigorous, globular, and good.

MARGARET DICKSON HAMILL (A. Dickson).—A real acquisition. A lovely deep yellow Rose tinted at the back with carmine. Blooms of good size; free, a good grower, and distinct. It is inclined to hang its head, but its blooms catch the eye at once, and deservedly so.

MRS. ARCHIBALD MACKEY (Hicks).—A fine deep pink, described as a larger and deeper Mrs. W. J. Grant. Likely to be a fine Rose for exhibition and also in the garden.

MRS. BERTRAM J. WALKER (H. Dickson).—A Rose I greatly like. Deep bright rosy-pink, of fine shape, quite full, but opens well; free, a big, fine Rose, and the habit is good in every respect.

MRS. FRANKLIN DENNISON (McGredy).—Creamy-white, but I had one bloom in the autumn a real yellow; makes good growth, and is very free. The blooms are pointed, here not extravagantly large, and so far it has not always opened well in this climate. But we had many mists the last two summers, and it may do better.

MRS. HUGH DICKSON (H. Dickson).—A finely-formed flower, creamy, with orange shading; very beautiful, free, of good size, and fairly vigorous.

MRS. MACKELLAR (A. Dickson).—Pale primrose, shading to a deeper hue towards the centre; of fine shape, vigorous, and an upright grower, holding its large blooms up well.

MRS. MAUD DAWSON (A. Dickson).—A good Rose, red, a fine grower, and very useful, though perhaps a trifle loose. The first blooms disappointed me, but the weather was probably the cause, as within a few good days it was much better.

SALLIE (B. Cant).—A good grower, rather in the style of St. Helena; creamy pink, deepening towards the centre, and touched with yellow. A good garden Rose, and said to be mildew-proof.

SOUVENIR OF HENRY GRAHAM (A. Dickson).—A well shaped Rose, of very delicate colouring, creamy, shaded with carmine; large, free, and fairly vigorous; very pretty. *L. C. R. Norris-Elye, Utterby Manor, Louth, Lincolnshire.*

(To be continued.)

POTATO BREEDING.

MR. ARTHUR W. SUTTON, in his paper on variation in the Potato, has shown that the evidence for the origin of a variety by mutation is far too scanty and lacking in scientific accuracy to warrant the belief that any of our domestic forms have originated in such a way from some pre-existing type.

Another point of interest, particularly to the Potato breeder, lies in the similarity of many of the varieties now upon the market, and the suggestion put forward that such similar or identical forms may represent the individual selection of different breeders from batches of seedlings, raised from parents of possibly widely different origin. In the absence of scientific records, and in view of the more or less haphazard and often none too careful methods of "seed" Potato distribution, it would be difficult to express any definite opinion on this question.

The following short list indicates some forms which closely resemble each other. Whether the resemblance is so complete as to be evidence of genetic identity I cannot positively say. No doubt many similar cases will occur to your readers.

	H.	Heliotrope; W.	White.
	VARIETY.	FLOWER.	TUBER.
1.	Factor .. / Up-to-date .. /	H., slight W. tips; no pollen.	W., long, oval, flattened; eye shallow, sprout with but slight colour.
2.	Abundance .. / Favourite .. /	W., no colour seen; very few pollen grains.	W., solid pebbles; eye somewhat marked; tend to scab; bluish purple sprout.
3.	Adirondack .. / Invincible .. /	No flowers seen.	Blush pink; solid, long or pebble; eye marked and deeper in colour.
4.	Flourball .. / Shamrock .. /	W., with slight H. below; quantity of pollen; sets seed-balls.	Solid, roundish, suffused pink; eye somewhat deep.
5.	British Queen / McPherson .. /	W., no pollen ..	W., solid, long; eye marked with brown.
6.	Langworthy .. / Peacemaker .. / Table Talk .. / What's Wanted /	H., W. tip; no pollen.	W., long, cylindrical, often tapering; eye shallow; strong cork; sprout purplish.

Each group in the above list appears to represent a particular combination of characters affecting foliage, flower, and tuber. A description which would make the character of the foliage of these varieties readily distinguishable is practically impossible. One depends upon the following characteristics to distinguish the foliar types met with; the number of pairs of leaflets, the presence of interfolioles, length of petiole and the distance between the insertion of successive pairs of leaflets, the shape, size, width, margin, surface, texture and apex of the leaflets, and also the size of the terminal leaflet.

It is not surprising that the difficulty of similar or identical forms has been met with in the Ormskirk trials, and the evidence accumulated during the course of scientific breeding would be of the utmost value and help. To call a form, a seedling of Up-to-Date, Factor, Langworthy or British Queen, for example, tells next to nothing as to its parentage, unless something is known of these varieties. These particular forms being sterile on the male side, cannot be made pollen parents, and for the same reason it is impossible to obtain selfed seedlings from them. Absence of seed-balls on these varieties is a definite and characteristic feature. Only when they are grown in close proximity to types bearing abundant pollen is there any chance of an occasional seed-ball being found. This season, at the John Innes Horticultural Institution, where numbers of varieties and seedlings were grown, and many with abundant pollen set innumerable seed-balls, one ball only was found on the "male sterile" forms. Six rows of Kerr's Pink, each of 20 plants, were grown, and the plant which bore this single berry was in an outside row and next the path. Putting aside the extremely improbable view that the flower from which the berry resulted had effective pollen, it is clearly evident that, although the plants raised from the seed of this berry might for convenience be termed seedlings of Kerr's Pink it is a loose term, and is not a scientific method of designating the parentage, as it fails to disclose the paternal element. Pollen from some other variety must be used in order to set seed in such "male-sterile" forms. Hence many and perhaps the majority of seedlings from cultivated varieties must be derived from cross-fertilisation.

My experience has been that seedlings raised from seed produced as a result of selfing those domestic varieties which have pollen, frequently bear a close resemblance to the parents in foliage characters, but rarely do well, lacking the vitality and growth which characterise the offspring resulting from cross-pollination. I believe that this must also be the experience of raisers of new varieties, and that they do not make any considerable use of selfed offspring.

There is the further problem of the origin and selection of early-maturing varieties. It is generally assumed that owing to the rapidity of growth and tuberisation many of the first earlies drop their buds or otherwise fail to flower, and only by resorting to unnatural cultural conditions can they be made use of in breeding. Even then the stamens are likely to remain ill formed, and the plant useless on its male side.

Facts derived from the scientific breeding of the Potato are accumulating, but still old varieties will masquerade under new names until law and order are introduced into distribution, and the pedigree of each new variety sent for trial is fully and accurately disclosed. *E. J. Collins.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Ground Operations.—Push forward the work of preparing ground for next year's crops, as recommended in the Calendar of November 9. Endeavour by tillage to obtain a soil of uniform quality and fair depth, and one containing the elements necessary for the successful growth of each individual crop. If drainage is necessary, this should be attended to; the depth and distance apart of the drains should vary according to the nature of the soil. As a rule, all soils with a subsoil of clay require draining in order to cultivate them to the best advantage. Charred refuse and burnt earth, mortar rubbish, road grit, and other similar materials, are all aids to fertility. The garden fire may now continue to burn in its own way, and if carefully replenished with fuel occasionally, a large heap of burnt earth may soon be had. At this season of the year all kinds of animal manure may be used in a tolerably fresh state.

Collecting Tree Leaves.—Forcing may be necessary on a much larger scale than usual next spring, and those who are in a position to collect an abundance of leaves can always turn them to good account in various ways. Hotbeds are required for forcing Asparagus, Seakale, Potatos, Carrots, and other crops, besides being of the greatest service in raising seedlings required for furnishing a kitchen garden. Oak and Beech leaves are the best, but for making ordinary hotbeds a general mixture with a little strawy litter is suitable. If good leaves are plentiful, a few loads collected in a sheltered place in the woods convenient for carting are better than large heaps placed in one place to ferment, for the leaves would lose their value before being required for use. If these heaps do not possess any marked fertilising properties they are of the greatest value for use in lightening heavy ground, if not required for the making of hotbeds.

Early Potatos.—A few early Potato sets should be placed in boxes to sprout in readiness for planting in pots or heated pits. Clear out the old hotbeds and replace them with freshly prepared leaves and litter. If plenty of leaves are available, the pits can be filled at once, treading them firm; fallen tree leaves will provide a gentle and lasting warmth, which will carry the tubers to maturity. When only a small quantity of new Potatos is required, pots are the best for very early forcing, as they can be stood in any early forcing house in a light position where the temperature ranges about 55°.

Seakale.—Where other vegetables are likely to be scarce, these roots may be made more use of after this date, as the crowns will now respond to gentle warmth. Treat the forcing roots as advised in the Calendar for November 2, also protect and prepare roots in the open as was recommended then.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Management of the Houses.—Great care must be exercised in regulating the temperatures and the atmospheric conditions of Orchid houses in winter; endeavour to maintain the temperature of each division as evenly as possible. During frosty weather, when much fire-heat is necessary, take measures to prevent the atmosphere from becoming excessively dry. On bright mornings following frosty nights, as soon as the temperature commences to rise to the proper degree, all bare spaces should be moistened thoroughly by syringing; the stages, spaces between the pots, the paths, and the floor underneath hot-water pipes should all be damped. Houses with paths formed of iron gratings or wooden lattice work over the natural earth will not require damping so much as those with paved or tiled floors. The East Indian, Cattleya and intermediate houses should be damped between 2 p.m. and 3 p.m. One damping should suffice in the Odontoglossum house, but the amount of atmospheric moisture should be regulated at all times in accordance with the weather.

Temperatures. — The night temperature of the various houses should be regulated as nearly as possible as follows:—East Indian house, 65° to 68°; Cattleya house, 58° to 63°; intermediate house, 55° to 58°; and Odontoglossum house, 48° to 52°. On very cold nights the lower temperature will suffice, as an excess of fire-heat is harmful to the plants. The houses should be warmest at mid-day. During very cold weather the temperature should be about 5° warmer at mid-day than in the early morning, but the thermometer may be allowed to rise several degrees higher during periods of bright sunshine. If lath blinds are fixed to the houses, they should be lowered during cold nights; if permanent blinds are not used, the glass may be protected by some other covering, such as canvas or Archangel mats. Their use will prevent the temperature from fluctuating, economise fuel, and keep the atmosphere from becoming very dry.

Ventilating.—Admit fresh air whenever it is possible to do so without lowering the temperature or chilling the plants. Air is best admitted through the bottom ventilators, which should be so arranged that external air will become warmed somewhat by passing over the hot-water pipes. The ventilators on the side sheltered from the wind should be opened first, and, as the temperature in the house rises, those on the other side should also be opened a little to cause the air to circulate freely.

Watering. Plants that have finished their growth should be allowed to become dry between each application of water at the roots, giving them only enough moisture to keep the pseudo-bulbs in a plump, rigid condition. Plants that are growing actively, and others that are pushing up their flower spikes, will need water on more frequent occasions than those that are resting.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Annuals in Pots.—Annuals should be largely grown for furnishing greenhouses and conservatories during spring and summer. There will be great demand for flowering plants of all kinds next year, and it will be wise to anticipate this demand by making timely preparation. Annuals of various kinds should be sown at once, and the seedlings grown slowly in cool houses. Those which have already been raised, such as Schizanthus, Clarkias, and Godetias should not be hastened into growth by the use of fire-heat. They will grow much more satisfactorily in cool houses, and fire-heat is not needed except to keep out frost. Annuals may be repotted at any time when they are sufficiently well rooted. Use a fairly rich compost and pot the plants firmly. Guard against aphides, which would cause much damage to the plants if allowed to spread; it is wise to anticipate attacks of the pest by lightly fumigating the houses at regular intervals. If dwarf plants of Clarkia are desired, pinch out the tips of their leading shoots.

Lachenalia. For the next few weeks Lachenalias should be grown in cool conditions, and as near to the roof glass in a shallow pot. They will succeed the better if the pots or pans are stood on a cool, moist surface, such as is provided by coal ashes or gravel. Ventilate the house freely during favourable weather, but do not expose the plants to cold draughts. Fire-heat will only be necessary to keep out frost.

Helleborus niger.—Flowers of the Christmas Rose will be more than ever acceptable this season. Where the plants are flowering in the open, the blossoms should be protected with frames or hand-lights, which not only keep the petals clean, but cause the flower stems to elongate considerably, thus making the blooms more useful for purposes of decoration. If necessary, a few roots may be lifted and placed near the roof glass in a house of moderate warmth.

FRUITS UNDER GLASS.

By W. J. GEISE, Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

Plums in Pots.—The earliest Plum trees in pots that were re-potted directly the fruits were gathered may remain out-of-doors until they are required for forcing. Care should be taken that the pots are well protected from injury by frost. During mild weather, thin the spurs where they are crowded, and carefully but thoroughly wash the trees down to their bases with strong soapy water or a solution of Gishurst compound. The end of the year will be quite early enough to commence forcing, but the trees may be brought indoors a little before they are started into growth, provided the house is kept cool and well aired.

Late Pot Plums. Should any of the late trees of Plums in pots need attention at the roots, whether it be by reducing the old ball of soil or by potting the plants afresh in a suitable compost, the work should be done forthwith. The ball of soil and roots may be pared smaller with a sharp knife, the old crocks removed, and the trees re-potted in a receptacle one size smaller, or they may be divested of all the old soil, the roots trimmed, and re-potted in fresh compost. Probably some of the trees may not need a fresh pot, in such cases the drainage should be made perfect, the old surface soil washed out down to the roots and replaced by a compost of loam, lime rubble, burnt earth or wood ash, and a sprinkling of bone meal. Whichever method is adopted, it is essential to make the soil quite firm. The trees may be placed out of doors on a dry, well-sheltered border, or returned to a cool house. The pots will need to be protected from frost if placed in the open.

Cherries in Pots. Cherry trees in pots intended to be started into growth in January should receive practically the same treatment as advised for early pot Plums. It is important for the present to maintain a low temperature and to keep the roots moist. Take precautions to protect the trees from birds, or many of the buds will be destroyed.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

Roses In order to have a few early blooms some of the Roses trained against walls, and especially the walls of hothouses or dwellings, may be pruned now and re-nailed. The pruning should not be so severely done as is usual in spring, but rather seek for and leave shoots that show buds in a forward state. All weak shoots should be cut clean out as being worthless for the purpose in view. A dressing of cow manure may be laid over the roots of the Roses, and during hard frost some protecting material placed in front of them, but not as a permanent protection. Blooms will be in to gather in April and May, though they will not be so large as those produced later in the season.

Thinning Shrubs. This is not the best time to examine and cut out the useless branches and shoots of flowering shrubs, but the exigencies of the times may have made it impossible to prune them at the proper season, and now, when there may be time to spare, it is worth while to overhaul them all. Just at this season I would advise only the thinning of shrubs, that is to say, the removal of all growths which obviously are of no value for flower production, and therefore a drain on the strength of the plant. Also, where a commoner or less valuable shrub is crowding a more valuable one, enough of the former should be removed to give both sufficient space to grow for a couple of years at least. Where it is possible to burn the prunings close to the shrubs, it saves a lot of time, and I have found it pay in this respect to lift enough turf to give space for a fire, returning the turf after the ashes have cooled.

Romneya Coulteri. A few flower buds are still in evidence on plants of Romneya Coulteri, but in most seasons the shoots are cut down to the ground by frost at this time of the year, and it is worth while to place some simple protecting material over the stools for the next eight or nine weeks. This plant is easy of increase by means of root cuttings, which may be taken now and placed in light soil in 4-inch pots. House the cuttings in a cool structure until the spring, when a little extra warmth will cause them to grow. The plant naturally produces offsets after being thoroughly established, and any of these that are in evidence may now be severed from the parent plant, the roots trimmed, and planted in a pot just large enough to contain the roots. These will be in fit condition to plant out in April or early in May, and will give late flowers the same year.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Scale on Pear and Other Trees.—As soon as the work of pruning fruit trees is completed, if there are any traces of scale insects, means should be at once taken to check and if possible to eradicate them. This pest is found more frequently on Pears and Plums against walls than on trees in the open. For bad infestations use a solution of soft soap (preferably carbolic), at a strength of 8 ounces to 2 gallons of hot water. Apply the specific whilst it is hot, with a new paint brush; so long as the finger can be kept in the mixture without discomfort it will not be too hot to harm the bark. Paint the bark thoroughly up to the buds, and lightly touch these. It is a good plan to have two lots of mixture in use, one being warmed over a slow coke fire whilst the other is being applied. Similar insecticide may be used on Peach and Nectarine trees for destroying the larger brown scale, but it need not be quite so strong or so hot, as these large scale insects are more readily killed. A form of white scale adheres very tenaciously, and is an insidious little pest to deal with, but as it is more easily detected than the mussel scale it may be attacked in good time. Two applications may, however, be needed to destroy this pest.

The Slug Worm.—This insect attacks Pears chiefly during the early summer, but I have noticed it as late as September. Finely slaked lime is an efficacious remedy in summer, but during the resting season it will be well to give the trees a dressing with lime-sulphur. I prefer to purchase this preparation rather than compound it, and it keeps well in a tin. Syringe the trees for this insect as soon as the pruning is done, and dust the ground under and near to the trees with finely slaked lime. This same preparation is an excellent specific for red spider and mildew.

Mealy Bug. I have only once seen this pest on out-door Vines, and in that instance I advised a thorough clearance to be made. It would be very serious if it attacked out-door Figs. I do not think any other hardy fruits are likely to be attacked by mealy bug. In any case, when total eradication is not deemed advisable, the best remedy is hot water applied as hot as possible by means of a syringe. Afterwards apply paraffin-soft soap emulsion. I have found mealy bug on Ivies near to fruit houses, and also on Ampelopsis Veitchii, hence if it be prevalent under glass it is possible for it to give trouble out of doors also. It is stated that there is a hardy form of this pest, and I am inclined to believe that this is true.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. - *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* EDITORS, 41, Wellington Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 9—
United Hort. B. & P. Soc. Com. meet

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 40.5°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, December 4, 10 a.m., Bar. 29.1; temp. 56°. Weather Dull.

The Chamber of Horticulture.

The formal inauguration of the Chamber of Horticulture, which took place on Monday, December 2, and of which a report is published on page 230, marks an epoch in the development of British horticulture. The fact that the first steps which led to the establishment of the Chamber were taken so recently as July of this year is an indication that the lessons of the war in showing the need for united action on the part of all sections of the horticultural industry have been learned and applied with energy and dispatch. No one who has profited by the experience of the past few years can doubt but that united and authoritative action by horticulturists is necessary if their industry is to receive the recognition and consideration which its scope and volume deserve. Those who have given time and energy in bringing this project to a successful issue deserve the thanks and congratulations of all horticulturists. They have proposed rules and articles of association which were submitted to the meeting, and they have also secured the promises of financial support amounting to no less than £1,200 a year for the next five years. Rarely, we believe, has so much work, and work of such far-reaching importance, been accomplished in so short a time; and the thanks of the horticultural world are due to Mr. Geo. Monro, jun., Mr H. Morgan Veitch, and those associated with them on the Organising Committee. But the work accomplished is but the preliminary to that which lies before the Committee and the Council to be elected as soon as a general meeting of delegates can be arranged. The scheme of work outlined at the inaugural meeting is a great one. It includes horticultural economics and research, inquiry into questions of transport with a view to increasing facilities for transit, removing grievances and anomalies, and reducing freight charges. But the great object of the Chamber, without the fulfilment of which none of the subsidiary objects can be achieved, is the binding together in one great fraternity all members of the many branches of the horticultural industry and the establishment of one central body which shall be able to negotiate with full authority on behalf of all sections of horticulture, to which the Government shall look for advice and assistance when questions affecting the horticultural industry are under consideration.

Mr. Prothero, the President of the Board of Agriculture, drew attention in his educative and encouraging speech to the need of the fullest means of co-operation between his Department and the Chamber, and expressed emphatically the view shared by a subsequent speaker that the Chamber has before it a long career of usefulness. Thus watched by the head of that Department of State whose special concern is the fostering of the horticultural industry, and supported by the trade itself, the Chamber has come into existence under happy auspices, and is, we feel sure, certain of universal support.

Horticultural Instruction. - The Food Production Department has appointed nine Divisional Technical Inspectors (three for fruit and six for vegetables and general cultivation), who have been instructed to get into touch with Horticultural Sub-Committees with the object of arriving at a common plan of action for securing that instruction and advice on technical matters relating to horticulture may be given on definite lines throughout the counties. The Department wishes arrangements to be come to with the R.H.S. and other bodies so that the whole country may be covered during the autumn and winter by lectures given on up-to-date methods. All applications for lectures to Allotments Associations, etc., must be made direct from the secretaries to the Horticultural Sub-Committee of the County.

Hampton Nursery Workers' Club. — The committee of the Hampton Nursery Workers' Club—the establishment of which is recorded on p. 221 of last week's issue of *Gard. Chron.*—has invited Mr. W. H. PAGE, chairman of the Hampton Nurserymen's Association, to become president. Mr PAGE'S desire to promote the welfare of all those engaged in horticulture, no less than the respect in which he is held by his fellow horticulturists, will make him an ideal president, and it promises well for the success of the club that he has consented to accept this office.

U.S.A. Embargo on Arsenic. - At the request of the United States Food Administration the U.S.A. War Trade Board has placed an embargo on the exportation of white arsenic. The chief purpose of this order is to protect American farmers and gardeners against a shortage of arsenical insecticides.

Gifts to the Rothamsted Experimental Station Library. - The Trustees of the Carnegie Trust have sent a cheque for £300 to the Library of the Rothamsted Experimental Station for the purchase of important reference books. This is the second donation made by the Carnegie Trustees to the Library, a cheque for a similar amount having been given two years ago. The purpose of their donation is to afford agricultural students and experts using the Library the opportunity of consulting the most recent and most important treatises on agriculture and allied sciences. Two other valuable gifts have been received, both from Captain the Hon. ROBERT GUINNESS. The Library is fortunate in possessing an unusually good collection of early printed books on agriculture of the fifteenth, sixteenth and seventeenth centuries; to these Captain GUINNESS has now added perfect and beautiful copies of the first and second printed books on the subject, viz., the great volume on agriculture by CRESCENTIUS, printed in 1471 at Augsburg, and JENSEN'S edition of the Latin agricultural writers, printed at Venice in 1472.

Re-Stocking War-Devastated Lands. — The Royal Agricultural Society has raised a fund of £150,000 to be applied to the purchase of pedigree and other stock for the purpose of re-stocking the devastated regions of France, Belgium and Serbia.

Dutch Firm's Jubilee.—The firm of C. G. VAN TUBERGEN, JUNR., Zwanenburg, Holland, is celebrating this year its fiftieth anniversary, and we have received an excellently conceived and executed souvenir, in the shape of a book, printed on art paper and freely illustrated, descriptive of the establishment and subsequent activities of the firm. One of the first illustrations is of the ancient farm of Zwanenburg, on the site of which the establishment still stands, but most of the old buildings are replaced by modern houses, and where sheep and cattle once grazed are now fields of brilliant blossoms. There are many illustrations of the numerous honours and diplomas gained by the firm at exhibitions in almost every European country for new varieties of Tulips, Freesias, Irises, and other bulbous plants. One of the pictures shows the PRINCE CONSORT of the Netherlands making a visit to the nurseries in 1908. It is an interesting group, portraying the four present members of the firm—Mr C. G VAN TUBERGEN, now an elderly man, Messrs J. M. C. and TH. M. HOOG, and THOMAS HOOG, JUNR., the eldest son of Mr. J. C. M. HOOG. It is a pleasant reflection that the jubilee of the firm is coincident with the return of peace, and readers will join us in wishing Messrs. C. G. VAN TUBERGEN, JUNR., an even greater measure of success than they have enjoyed in the past.

Forestry Training at Edinburgh.—The Edinburgh University Court has approved of a scheme made by arrangement with the War Office, by which the Forestry Department will be given facilities for the use of the woods and forest tree nursery at Dreghorn Estate for a forest garden for the training of students in forestry in connection with the University.

The Fuel Problem.—In view of the shortage of coal for horticultural purposes this winter, the following hints for preserving greenhouse plants until the return of warmer weather may be valuable to amateur gardeners. They have been sent by the Rev. W. WILKS, secretary of the Royal Horticultural Society: Go through the stock and throw away any surplus plants. Close the others up into the smallest available space in the most easily heated house. Calculate the amount of fuel at disposal and arrange for it to be equally distributed so as to keep up a uniform temperature, not less than 45°, or more than 50°. Keep all the plants very dry, and do not throw water about the house, or paths, or stages. Keep the ventilators closed except during bright, sunny weather. Carefully stop all openings in the roof, etc., through which cold currents of air might come. Arrange to "mat" or otherwise cover the outside of the house before really hard frosts set in. This may be done on the outside with old matting or sacking, and on the inside keep ready beforehand a good sup-

ply of paper (old newspapers, etc.), and lay them lightly over the plants, resting on the leaves. These may be removed during mild weather and replaced at return of frost. Specially rare or tender plants should have a fold or two of paper wrapped around them and the paper retained until the spring. The most effectual safeguard is to keep all plants dry, only giving a very little water at wide intervals. Particular care should be taken not to alternate warm and cold treatment when fuel is to be had some times and not at others. Begin cold treatment and maintain it uniformly. As an extreme measure in the case of Orchids it would be possible after the plants had been allowed to become thoroughly dry to turn them out of their pots, remove the potting material, wrap each plant in one or two folds of paper, and place them closely together in large boxes (as though they were to be sent away as goods); place the lids on in such a way that a little ventilation is provided, and store in a warm, dry shed or loft until the severe weather has passed, when they can be removed, repotted and placed in the house to grow again. Such treatment would be only what Orchids have to undergo during import or export.

Brasso-Laelio-Cattleya Antoinette. — The experienced hybridist is prepared for unexpected results, but in some cases the evidence of the parentage recorded is so difficult to trace that its correctness is questioned. The fine Brasso-Laelio-Cattleya Antoinette Gatton Park variety, for which Sir JEREMIAH COLMAN, Bart., was awarded a First-class Certificate at the Royal Horticultural Society on November 5, is a very notable instance of the domination of one parent to the almost complete exclusion of the features of the other. B. L.-C. Antoinette was raised between Cattleya Portia (*coerulea* (*labiata coerulea* × *Bowringiana*) and Brasso-Laelia Helen (B. Digbyana × L. *tenebrosa*), the latter having rather long, lanceolate sepals and petals, and a form quite the opposite of the model flower produced in the cross. The only suggestion of Brasso-Laelia is the slight fringing at the margin of the lip, the main characters of the flower being of C. Portia, with an enlargement of all its parts; the colour is bright rosy-mauve with reddish purple front to the lip, the varying tints being almost impossible to indicate in a photograph. At the meeting of the Royal Horticultural Society on November 19, another plant of the batch was shown, the flower being of the same character as that illustrated in fig. 91, but the plant had the hard, slender pseudo-bulbs of Brasso-Laelia Helen, and adequately proved the correctness of the parentage recorded.

War Items. The friends of M. HENRI NONIN will be interested to learn that he has been promoted to the rank of 1st Lieutenant, and that his connection with the American Forces has now terminated. He has returned to his regimental depôt.

Mr GUY NEVILLE, a former member of the Kew Garden staff, has returned safely from Germany. When war broke out Mr. NEVILLE was studying viticulture on the Rhine, and was interned in Ruhleben Camp.

In order to assist the funds of the Society for the relief of horses wounded and broken in the war, of which the Duke of PORTLAND is the President, the Duchess of PORTLAND has taken several shops in various parts of the West End of London for the sale of gifts sent by her friends. A large shop in Regent Street is devoted to the sale of choice fruit and vegetables, where a large business is being conducted in the sale of these commodities. The window of the shop has been attractively arranged by Messrs. SUTTON AND SONS, and the unusual display has caused such interest that the pavement has often been blocked by those inspecting the window.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Bud Variation in Potatos.—The paper upon this subject which was delivered by Mr Arthur W. Sutton, at the Ormskirk Potato Conference on October 31, does not state actual facts correctly. Mr Sutton has apparently failed to grasp the position of the careful investigator in this important and interesting problem in regard to the Potato. I am not concerned with his interpretation of Nature and her laws, nor shall I attempt to criticise his philosophy. He makes one statement, however, which I lose no time in controverting. It is as follows: "But those who claim that new and distinct varieties have arisen by bud variation assert that, from the earliest stages of growth above ground, the so-called new varieties are wholly and completely distinct from their neighbours in the plot." He then goes on to say: "The fact, however, is that we have been advised not to remove plants which we call 'rogues' from a crop of Potatos, because they may be new and distinct varieties which have arisen by bud variation immediately gives the lie to the whole claim, as in every instance where it is said a new variety has so arisen, the whole of the tubers at the base of the plant when lifted differ entirely from the tubers in the plot, and, moreover, are all like one another." As one who claims to have obtained mutants from certain varieties of Potatos, I state, and state emphatically, that they have been obtained as odd tubers on a stolon bearing all other tubers true to type of the particular variety which the seed set represented. "Rogues" are another matter altogether. If mutants, however, are not observed, and are passed with ordinary seed tubers for use in the ensuing planting season, they become "rogues." Those interested in this problem are quite aware that all so-called "rogues" are not what they are popularly supposed to be. As I stated in my last note on this subject, however, accuracy is essential before we can say which is a "rogue" and which is not. I have two instances this season—thanks to careful observation when lifting—of totally different types to the parent on a stolon otherwise throwing tubers true to type. *George M. Taylor, Mid Lothian.*

Home Oil Production.—The Flax, the seed of which contains 34 per cent. of oil (Konig), and the Sunflower, unshelled seed of which yields 31 per cent., and shelled seed 44 per cent. of oil, have been popularised of late. Another oil-producing plant which the Germans and Austrians grow largely is the garden Poppy (*Papaver somniferum*). According to Konig the seeds yield 40·8 per cent. of oil; according to the *Encyclopedia Britannica* 30·40 per cent. by cold pressing, with a total of 50·60 per cent. a heavy yield; it seems to be indifferent whether the seeds be dark or pale. Besides being put to technical uses the oil is largely employed as salad oil, and it is perhaps significant that many bottles from the grocer bear the legend "Best salad oil," not, be it noted, "Olive oil." As a few casual plants came up in my garden they were left to seed in order to see what yield they would give. Five plants, one a fairly large branched one, the others medium or small in growth and development, yielded no less than 3½ ounces of seed. Since the specific gravity of the oil is given at 0·9249, it is clear that not many dozen plants should be required to obtain a pint of oil. Grown on a small scale the plants and their pods could be kept upright, so that the seeds would not fall out of the capsules. *B. E. D.*

FIG. 91.—BRASSO-LAELIO-CATTLEYA ANTOINETTE GATTON PARK VARIETY: COLOUR BRIGHT ROSY MAUVE, FRONT OF THE LIP REDDISH PURPLE.

SOCIETIES.

THE CHAMBER OF HORTICULTURE.

THE Chamber of Horticulture is now an accomplished fact, and it will be legally entitled to take its place in the world of horticulture as soon as the Articles of Association have been registered. The inaugural meeting was held at Caxton Hall, Westminster, on Monday, December 2, and proceedings commenced about four minutes after the advertised time—2.15. Mr. George Monro, junr., presided, and there were between 150 and 200 people present. On the platform, with the chairman, were the Rt. Hon. R. E. Prothero, President of the Board of Agriculture; Sir Henry Rew, Permanent Under-Secretary of the Board of Agriculture; Dr. F. Keeble, Controller of Horticulture; Mr. A. G. L. Rogers, of the Horticultural Section of the Board of Agriculture; Mr. W. Joynson Hicks; Mr. F. R. Ridley, London Fruit, Flower and Vegetable Markets Association; Mr. H. Morgan Veitch, Mr. Arthur W. Sutton, Mr. Joseph Rochford, Mr. J. S. Brunton, and Mr. Moore, hon. treasurer of the Chamber.

Mr. Prothero, who was the first speaker, had a hearty reception. He said he was pleased to be present at the establishment of the Chamber of Horticulture, especially as it gave him the opportunity of thanking the members of the horticultural trade for the way they had accepted Orders made necessary by the war, and of thanking Dr. Keeble for all he had done for him, for the trade and for the nation. If the Chamber was to be a successful and powerful influence in the industry its foundation must be laid on broad and comprehensive lines that would embrace every section of the trade. Established on such lines, it would be valuable for two reasons. Firstly, because it would give to Horticulture that unity which makes for strength not only to the industry as a whole, but also to every part. Secondly, because it would be a direct channel of communication between the Board of Agriculture and the trade; the Board would help the Chamber; the Chamber would greatly help the Board, and he hoped the two would work together. The work of the Advisory Committee had shown the value and need of co-operation with those intimately connected with commercial horticulture and it had rendered splendid service during the war. Now, under altered conditions, the Chamber would take up much of the work. There were many ways in which help could be afforded. In horticultural research we had lagged behind some other peoples, but if we were bad starters we were good finishers. In connection with fruit cultivation there was ample scope, and he hoped that scientific research, carried on by the Chamber and the Board, would soon make good any deficiencies and set a pattern for others to follow. The eradication and control of diseases and insect pests were matters of immense importance in which the co-operation of the Chamber would be very helpful because of the practical experience which it would bring to bear upon them. In regard to railway and other means of transport, the Chamber would be able to do what persons and special societies could not do on piecemeal lines. In conclusion Mr Prothero considered that the Chamber of Horticulture and the Board of Agriculture together would form a powerful instrument for the advancement of horticulture; he desired to see such a Chamber established and every section of the trade co-operating to make it effective.

Mr Prothero's speech was heartily applauded, and he was thanked before leaving to fulfil another engagement.

Mr. Ridley, in a few appropriate words, emphasised the need for focussing the energy of every section of the trade by means of a central Chamber, and he proposed "That this meeting of representatives of commercial horticulture in all its branches heartily welcomes and supports the inauguration of the Chamber of Horticulture." Mr. W. Joynson Hicks, who for many years has been Member of Parliament for the large market-gardening district of Brentford, seconded the motion, and submitted that few people understood how much the market growers had done in providing food for the nation during war-time. The industry did not hold the position it deserved. He suggested the Chamber should be the guiding spirit in the training of home-coming men who desired to take up commercial gardening as a means of livelihood. Every other industry had its Chamber, and he was glad horticulture had now come into line. The question of transit was of exceptional interest to commercial horticulture, and the Chamber should press for the reconstruction, improvement and extension of good roads, as well as better railway facilities and reasonable rates. To be a success the Chamber must, he submitted, be representative and universal; no section and no interest should be omitted. There should be no standing aside because of selfish motives. The idea should not be "I can get nothing out of it," but the unselfish one of helping so that the industry as a whole would benefit. All should join, all act as missionaries, secure a Council in whom the trade would have confidence, and then back it to the fullest extent. The motion was then put and carried unanimously.

Mr. Monro then outlined the aims of the Chamber, and especially referred to the fact that the Chamber desired to encourage all sectional and local trade bodies connected with horticulture. He believed there were not enough of such societies: it had taken war conditions to awaken some sections of the trade to the need of organisation. The Chamber would not interfere with the "home rule" of these societies; it would, by their inclusion, be strong enough to exercise a powerful influence in the interests of all. With the Chamber as guide, Government control could be so influenced that it would give the greatest national advantage at the least cost and the least disturbance of trade. Transport, imports, and Parliamentary matters would all receive full consideration by the Chamber. As regards statistics, horticulture was in an almost hopeless condition, and one of the first things the Chamber would consider was the compilation of statistics which would serve to show the extent of the industry and give a fair idea of the capital involved, labour employed, and material produced. It was hoped that the Chamber would soon have a building of its own with room therein to accommodate the secretariats of the trade societies having London offices. As regards finance, business men had, as a business measure, guaranteed an income of about £1,200 a year for five years.

Sir Henry Rew supported the formation of the Chamber, and admitted that horticultural statistics were far from complete, but he believed the market-gardening industry held about 1,000,000 acres, and the value of the produce at 1913 values was about £17,000,000, exclusive of glass production, flowers, and the nursery trade. It would be a sound policy on the part of the Chamber if it collected facts (not always a popular business) relating to the trade and then proceeded with legislation, instead of legislating first and then getting the facts.

Dr. Keeble said that had the Chamber of Horticulture been formed two years ago it would have been able to render great service, and a great deal of loss incurred would have been saved. He considered the step taken that afternoon was a fortunate and wise one in view of the difficult reconstruction period ahead. He believed in the long run horticulture would prove to be one of the greatest of our national industries, but at present there were no statistics to show its importance—nothing but estimates. An economic investigation of horticulture could only be obtainable through a Chamber of Horticulture. Rural re-population would soon solve itself if statistics were forthcoming. For instance, a farm of 150 acres of mixed arable land, in the Midlands, employed five men ten years ago; now it had 30 acres under market gardening and fruit, and 20 men were employed, besides 150 pickers in fruit harvests. In 1851 three men and a boy were employed on a 150-acre holding, and the wages were 15s. per week for the men. In two years this holding under market gardening and fruit, employed 20-25 men and 30-100 women, and the men's wages rose to 20s. The holding was increased to 310 acres, and under intensive cultivation it gave employment to 90 men in winter, 110 in spring and summer, and 50 women, and the annual wages bill came now to £10,600. The question of land settlement should be on sound lines, and statistics were needed for guidance. There was little to show the average cost of crop production; no figures to show what were the best Apples for certain districts, and their rate of growth and production. In these and so many other directions the Chamber of Horticulture would be able to investigate and provide the necessary figures, and he therefore wished it a long, busy and profitable career.

Further approval came from Mr. A. G. L. Rogers, who suggested that nomenclature of fruits, Potatos, and vegetables (in reference to duplication of names) was a subject the Chamber might take up, as well as the proprietary rights of raisers of new fruits, flowers and vegetables.

Mr. H. Morgan Veitch, in a very capable speech, outlined the Rules and Articles of the Chamber, pleaded for the combination of all sections of the trade, suggested a labour register, a conciliation board, and the possibility of increasing the interest in horticultural charities, and he proposed "That the Organising Committee is hereby authorised and requested to register the Chamber of Horticulture under the Companies Acts with Memorandum and Articles of Association, and that such Committee do act as the Council until the election of the first Council by the members." Mr. W. Seabrook seconded the resolution, which was then carried unanimously.

Mr. C. H. Curtis stated that the establishment of a commercial horticultural library was one of the aims of the Chamber, and he asked for contributions of horticultural works so that the nucleus of a good library might be formed by the time the Chamber was suitably housed. A vote of thanks to the chairman, moved by Mr. Wm. Poupart, brought the meeting to a close.

ROYAL HORTICULTURAL.

DECEMBER 3.—At the meeting held in the London Scottish Drill Hall on this date there was a fair attendance. The exhibition was small but quite good, owing, chiefly, to the presence of many handsome Orchids, one group of these plants obtaining a Gold Medal. Other flowers displayed were Chrysanthemums, Ferns, Winter-flowering Begonias, and a few hardy plants.

The Fruit and Vegetable Committee had no business to conduct. The Floral Committee granted three Awards of Merit and four medals, and the Orchid Committee awarded a Gold and one other Medal, two First-class Certificates, and two Awards of Merit.

Floral Committee.

Present: Messrs. H. B. May (in the chair), E. A. Bowles, S. Morris, G. Reuthe, C. R. Fielder, Wm. Howe, F. Page Roberts, John Heal, Geo. Harrow, Thos. Stevenson, Chas. E. Pearson, Arthur Turner, J. W. Moorman, George Paul, C. Dixon, H. J. Jones, John Dickson, E. F. Hazelton, W. P. Thomson, R. C. Notcutt, A. G. Jackman, E. H. Jenkins, W. G. Baker, and J. F. McLeod.

AWARDS OF MERIT.

Chrysanthemum Bronze Molly.—A large-flowered single variety and a counterpart of Molly Godfrey, from which it is a sport, in all but colour. The ground colour is yellow, and this is overlaid with carmine, but the general effect is golden bronze. Shown by Messrs. W. J. GODFREY AND SON.

Chrysanthemum Mrs. H. J. Jones.—This is a large, bold, and shapely single variety with broad, firm florets. The colour is palest blush with a slightly deeper hue at the tips of the florets. Shown by Messrs. H. J. JONES.

Carnation Brilliant.—Judging from the plants submitted, this is a free-flowering Perpetual Carnation of good habit. The large blooms are deep scarlet and the margins of the broad petals are slightly fringed. Slightly scented. This variety also obtained a Certificate from the Floral Committee of the British Carnation Society. Shown by Messrs. STUART LOW AND Co.

GROUPS.

A bright little group of Chrysanthemums, staged by Messrs H. J. JONES, Ryecroft

Nursery, Lewisham, contained beautiful blooms of Alfie, Beacon, the new, blush-coloured Mrs. H. J. Jones, Bronze Beauty and Daybreak among singles, and Princess Mary among Japanese varieties. (Bronze Banksian Medal.) Another effective group of these flowers was set up by Messrs. W. J. GODFREY AND SON, and in this the new golden-bronze Molly Godfrey, a large single, was the principal variety, in association with Dora, Captivation, Audrey, and Queen of the West. (Bronze Banksian Medal.)

Messrs. S. LOW AND CO. exhibited a group of about twenty varieties of Perpetual Carnations, each represented by a dozen or eighteen blooms of good quality. (Bronze Flora Medal.) Mr. G. REUTHE showed various interesting shrubs, and Messrs. H. B. MAY AND SONS grouped Ferns of many kinds with a few semi-tuberous winter-flowering Begonias and Cyclamen. (Silver Banksian Medal.)

Orchid Committee.

Present: Sir Jeremiah Colman, Bart., in the chair; Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), W. Bolton, W. H. White, R. A. Rolfe, C. J. Lucas, A. McBean, W. H. Hatcher, S. W. Flory, J. Charlesworth, E. R. Ashton, W. J. Kaye, T. Armstrong, Fred Sander, Frederick J. Hanbury, and Pantia Ralli.

AWARDS

FIRST-CLASS CERTIFICATES

Brasso-Cattleya Catton Lily (C. Trianæ albens × B.-C. Daphnæ Mendelii var. Fortunæ), from Sir JEREMIAH COLMAN, Bart., Gatton Park, Surrey (gr. Mr. J. Collier). A handsome hybrid with large, pure white flowers, the front of the lip having a veined band of bright violet and a clear yellow disc. The petals are the broadest seen in this section. The spike bore two flowers.

Cypripedium John Hartley (Reginald Young × Shogun), from JOHN HARTLEY, Esq., The Knowle, Morley, Yorks.—A fine Cypripedium originally described in *Gard. Chron.*, December 1, 1917, p. 218. The variety has already been awarded a Silver Medal and First-class Certificate by the Manchester and North of England Orchid Society. The noble flower has much of the character of C. insigne Harefield Hall, the dorsal sepal, which is 3½ inches across, being pale yellowish-green, blotched with purple, the upper third pure white; the lip is greenish-yellow, tinged with rose.

AWARDS OF MERIT

Laelio-Cattleya Marshal Foch (L.-C. Myrtha × C. Luegeae), from Messrs. CHARLESWORTH AND CO., Haywards Heath. A delicately tinted flower of goodly proportions. The sepals and petals are pale chrome-yellow, tinged with rose; the lip is yellow veined and tinged with purple in front.

Laelio-Cattleya Linda Beguin, variety (L.-C. Arachne × C. Dowiana aurea), from Dr. MIGUEL LACROZE, Bryndir, Rochampton (Orchid grower, Miss Robertson). A pretty variety of the hybrid illustrated and described in *Gard. Chron.*, November 9 last, p. 189, and resembling it in form. The sepals and petals are rose-coloured with a yellow shade; the lip is ruby-purple with gold veining from base to centre.

PRELIMINARY COMMENDATION

Odontoglossum Racina (eximium × Lady Pirrie), from Messrs. CHARLESWORTH AND CO. The flowers are a rich claret colour with clear white margin; the lip is white in front, the base dark purple, and the crest yellow.

Odontioda Marshal Foch (Charlesworthii × Euphtelaea), from Messrs. ARMSTRONG AND BROWN. A remarkable cross between two noted Odontiodas and resulting in a perfect flower of deep claret-red colour. The crest of the lip is yellow with a large blotch of dark red in front, the apex being rose, spotted with red.

OTHER EXHIBITS

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, were awarded a Gold Medal for a collection which was probably the finest group of the year. The exhibit contained two hundred and twenty-five specimens of rare Cattleyas, Laelio-Cattleyas, Odontoglossums, Odontiodas, and others. The centre of the group was composed of Cymbidiums, with tall sprays of yellow Oncidium varicosum and occasional plants of good forms of Laelia anceps arranged in prominent places; in the front of the exhibit were fine forms of Cypripediums. The best novelties were Brasso-Cattleya Digbyana Mendelii var. President Clemenceau (C. Mendelii alba × B. Digbyana), a good, white flower with emerald-green centre to the lip; Cattleya Maggie Raphael var. Marshal Foch, a grand, pure white flower with broad, violet-purple lip and gold disc, and resembling the best form of C. mardyana alba; Odontioda President Clemenceau (Odm. Wilckeanum × Oda. Charlesworthii), with Indian-red sepals and petals slightly tinged with gold, and a broad, mahogany-red lip with white-fringed margin bearing a few spots. A handsome plant of a fine form of Odontoglossum eximilus with a spike of twelve finely-coloured flowers was included in the display, also various seedlings flowering for the first time.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a group containing a good selection of novelties, also specially good Odontoglossums and Odontiodas, among which we noted Odontoglossum plumptonense (amabile × Lambeauianum), beautifully blotched with claret colour on a white ground, and O. Prince Edward (crispo-Harryanum × Rolfeae). Ordinary forms shown were blotched with purple, but one was an albino with pale coloured markings.

Sir JEREMIAH COLMAN, Bart., exhibited flowers of Cochlioda gattonense speciosa × Sanderae with pretty white flowers showing the ridges of C. speciosa in the lip; and an interesting cross between Cattleya Adula and C. Dormaniana named C. Adula Dorman.

FREDERICK J. HANBURY, Esq., Brockhurst, East Grinstead, sent for recording a flower of Dendrobium Hanburyi (Dalhousieanum × Smithianum oculatum) yellow in colour, with a maroon-coloured disc to the lip.

Dr. MIGUEL LACROZE showed Laelio-Cattleya Linda aurifera with yellow sepals and petals; and L.-C. Linda illuminata.

Messrs. FLORY AND BLACK, Slough, showed the new Brasso-Cattleya Ruby (B.-C. Mrs. J. Leemann × C. labiata Peetersii), the bright, rosy-mauve flowers having a gold-veined disc to the lip; a good form of B.-C. Nestor; and some pretty unnamed hybrid Cypripediums.

Messrs. STUART LOW AND CO., Jarvisbrook, showed Cattleya Alcimeda alba; varieties of C. Gaskelliana, and Sophro-Cattleya Doris with three good scarlet flowers on the spike.

Messrs. J. AND A. MCBEAN, Cookbridge, staged a selection of Indian Odontoglossum crispum xanthotes, Odontioda Charlesworthii xanthotes, and the new Cymbidium Caroline Doris (erythrostylum × Lowianum).

Fruit and Vegetable Committee.

Present: Messrs. J. Cheal (in the chair), Owen Thomas, E. A. Bunyard, W. Bates, W. G. Weston, E. Beckett, A. Bullock, A. R. Allan, H. Markham, F. Perkins, P. W. Tuckett, W. H. Divers, George P. Berry, and Ed. Hurtess.

BRITISH CARNATION.

DECEMBER 3. This Society, formerly the Perpetual-flowering Carnation Society, held its first annual meeting under the above title at the offices of the British Florists' Federation. Mr. J. S. Brunton presided over a very small attendance of members, not many more than a dozen being present.

The annual report and financial statement were presented and adopted. In the former, special reference was made to the Floral Fair in Trafalgar Square on June 20 to June 26, when the members of the Society provided flowers which realised over £200 for the British Ambulance Funds. Although membership has diminished the Society is in a sound financial position, as there were no expenses incurred by exhibition. The turnover was £110 1s. 9d., and the balance carried forward is £52 5s. 10d., the largest the Society has ever had at the conclusion of a year's work.

The officers were all re-elected, viz., Lord Howard de Walden, president; Mr. J. S. Brunton, chairman; Mr. W. Wallace, vice-chairman; Mr. A. C. Cook, treasurer; and Mr. T. A. Weston, secretary. The latter is still in khaki, but has carried on the business of the Society with the help of his wife; he was voted an honorarium of 12 guineas. The retiring members of committee were re-elected, except that Messrs. Lay and P. Bunyard take the places of Mr. Grubb and the Rev. J. Jacobs.

The meeting agreed that a show should be held, if possible, at the end of April, 1919, and also decided that a conference should follow the meeting of the General Committee on January 28 next. We understand Mr. Wallace, of Eaton Bray, has promised to read a paper on the last-mentioned date.

CROPS AND STOCK ON THE HOME FARM.

BASIC SLAG ON GRASS LAND.

Basic slag has such a marked effect on the growth of grass that I offer no excuse for again referring to the subject. A thick crop of Clover quickly follows a dressing of slag on land which previously had never been known to produce Clover. November is the best month in which to apply this fertiliser, as the winter rains slowly wash the particles down to the roots of the grass; the good effects of an application are noticeable in the first year in the growth of Clover and the smaller grasses.

Some writers advocate the use of 8 cwt. of slag per acre; personally I would rather apply this quantity in two dressings with an interval of two years; the larger quantity is too much for effective assimilation, and half the quantity on two occasions gives better results. Before sowing the slag the surface soil should be worked with heavy iron harrows. It is possible to sow basic slag by hand in small quantities, but it is much more evenly spread if a proper distributor is used. Cattle should not be allowed to graze the grass for quite three months after the slag is sown.

THE 1919 POTATO CROP.

Now is the time to commence the preparation of the land for next season's Potato crop. Too often the soil is not sufficiently exposed to the weather, especially in the case of heavy land, which requires much more amelioration than light loam. Stiff land should be ploughed extra deeply, in order to drain the surface and render the soil warmer. Farmyard manure should be ploughed in during the autumn, but not too deeply, as it then mixes thoroughly with the soil during further spring ploughings. No doubt the best results are obtained with farmyard manure, artificial fertilisers used at planting-time, and thorough cultivation during all stages of growth. *E. Molyneux, Swanmore Farm, Bishop's Waltham.*

F.P.D. SEED WHEAT.

IN response to numerous enquiries the Food Production Department states that the varieties of selected seed Wheats of the 1918 crop, of which there are small stocks still to dispose of, are Browick, Rivett, and Little Joss. The prices are 97s. per quarter of 504 lbs., f.o.r. at the distributing agent's station, bags 2s. 6d. extra each. Orders may be placed through the Food Production Department, 72, Victoria Street, S.W. 1, but no money should be sent to the Department; preferably farmers should order through their local corn or seed merchants. All the varieties of Wheat mentioned are heavy croppers, and they have been selected from a wide range of soils, the seed being carefully re-cleaned and tested for germination and purity by the Department. Little Joss has proved very successful on every kind of soil, and is particularly suitable for light land in exposed situations and late districts.

Obituary.

Henry Fox. We regret to announce the death of Mr. Henry Fox, gardener for the past 16 years at Ripley Castle Gardens, Yorkshire. He was the son of the late Mr. Thomas Fox, at one time gardener at Wilton Castle, Yorkshire. Mr. H. Fox commenced his gardening career in the gardens of Pain's Hill, Cobham, Surrey; he was next employed at Burwood House, the residence of the late Dowager Lady Ellesmere, and from there went to Wexham Park, Slough, as foreman under Mr. James Ford. In the same capacity he was subsequently employed at Caversham Park under Mr. Jeffries, and afterwards obtained a similar appointment under Mr. Divers at Ketton Hall, near Stamford. His first charge as head gardener was at Kingswood, Sydenham, the residence of J. Lawson Johnston, Esq. Later he was gardener at Batteshall Mount, Worcester, the residence of the Hon. Percy Allsopp. He eventually succeeded Mr. Tunnington at Ripley Hall, 16 years ago. The funeral took place on the 24th ult. in Ripley Churchyard, where the large attendance of friends testified to the regard in which Mr. Fox was held.

R. P. Gregory.—Botanical science has suffered a severe loss in the death of Mr. Reginald Philip Gregory, which occurred on November 24 from pneumonia following influenza. Mr. Gregory, who was 39 years of age, was born at Trowbridge, Wiltshire. Educated at Weston-super-Mare, he entered St. John's College, Cambridge, as a scholar in 1898, and, after distinguishing himself in the Natural Science Tripos, devoted himself to teaching and research. He was one of the young men who took up with enthusiasm the investigation of practical problems under the leadership of Prof. Bateson, in collaboration with whom some of Gregory's work was published. The wonderful series of investigations into the genetics of Primula sinensis begun by Bateson was continued with brilliant results by Gregory. In this connection his discovery of the fact that giant races have this character reflected in their cell structure, in that the cell nucleus has twice as many chromosomes as is contained in the nucleus of cells of normal races is of great interest. Gregory's published work is characterised by a precision of which only great workmen have the secret, and, indeed, he was in the true sense a great work man—one who devoted his life to producing well-finished pieces of work. Thus he had already laid the foundation of a high reputation, and those who watched his career closely were convinced that he would have done yet greater things had he been spared. Fate has willed it otherwise, yet his friends—and they are many—who mourn his untimely loss have this solace, that since "long lives the creative work of all practical men," Gregory will be remembered not only by the regard and affection which he inspired but also by the work which he accomplished.

Robert M'Murdo. We regret to announce that Mr. Robert M'Murdo, market gardener, Glasgow Street, Maxwelltown, died on the 28th ult., in his 80th year. Mr. M'Murdo served his apprenticeship with Messrs. T. Kennedy and Co., nurserymen, Dumfries, and began business as a market gardener in Maxwelltown 54 years ago. He is survived by his widow, and two children out of a family of seven.

Augustin Gravereau. We regret to announce that Monsieur A. Gravereau, the well-known nurseryman and seedsman, of Nemphle le Château (Seine et Oise), France, died on the 23rd ult., aged 55 years. Monsieur Gravereau, who was vice-president of the Old Students' Association of the National Horticultural School at Versailles, specialised chiefly in the production of seeds of Marguerites, Pansies, Zonias, Nemesia, and Gladiolus. A number of new strains of these plants of great value owe their origin to his labours. Among Gladioli he raised the pretty and curious variety "Triomphe de Paris." During the war Monsieur Gravereau devoted all his time to the service of his country as local inspector of agricultural labour and President of the Reconstruction Committee. A. M.

Alfred Osborn. News has reached us of the death, on November 26, at West Croydon, of Mr. Alfred Osborn, after a long illness, patiently borne. Deceased was for a considerable period gardener at Hunts'land, Crowley Down, Sussex.

MARKETS.

COVENT GARDEN, December 4.

Plants in Pots, &c.: Average Wholesale Prices.

(All 48's, per doz. except where otherwise stated).

	s. d.	s. d.

— small 60's ...	3 0	3 6
— 72's, per tray of 16's	2 0	2 6

REMARKS. Business is getting more brisk in this department now; a larger variety of flowering plants are on sale. Hyemalis are the most attractive in Ericas. Other flowering plants consist of Begonias, Chrysanthemums, Marguerites, Cyclamen, and Solanums. Ferns and Palms of various sizes are going out freely. A limited quantity of Roman Hyacinths bulbs are soon bought up.

Cut Flowers, &c.: Average Wholesale Prices

— Sunburst ...	6 0	8 0
Violets, single, per doz. bun. ...	0 6	0 12 0

REMARKS. White flowers are still in great demand, but on Saturday morning prices were considerably lower before the close of the market, especially amongst Chrysanthemums, both for spray, bunch and disbudded blooms. Roses are gradually getting scarcer, and prices are quickly rising for the best blooms. White Carnations are still high in price, but coloured varieties tend to a slight reduction. Lily-of-the-Valley has become very scarce during the last few days. A few bunches of Roman Hyacinths made a fair substitute, and were soon purchased. A few boxes of Narcissus Soleil d'Or are arriving in excellent condition from the Channel Islands. Some French Paperwhite Narcissus and Violets, including large bunches of Parmas, arrived last week, but the supply so far is very irregular. Owing to the mild weather the single Violets are not to be recommended after such a long journey.

REMARKS. The market continues to be well supplied with Grapes, including some Colmar, Black Alicante, and Almeria, but supplies of Muscat of Alexandria are, as usual at this time of year, limited. Among dessert Apples Cox's Orange Pippin is the chief sort. The following varieties of cooking Apples are available:—Bramley's Seedling, Dumelow's Seedling, and Newton Wonder. Tomatos and Cucumbers are now limited in supply, but Mushrooms are rather more plentiful. Green vegetables are abundant. *E. H. R., Covent Garden Market, December 5, 1918.*

GARDENING APPOINTMENTS.

Mr **J. C. Ash**, for the past 12 years Gardener to the late W. W. Howard, Esq., Highwood, Mill Hill, Middlesex, as Gardener to Mrs. F. M. Butler, Cotswell Manor, Faringdon, Berkshire.

Mr **J. S Buckby**, for the past 2½ years Gardener to Henry Beecham, Esq., Forest Hill, Hartford, Cheshire, as Gardener to the Rev. E. Earle, Bilton Grange, Rugby. (Thanks for 1s. for R.G.O.F. box.—Eds.)

Mr **F. Cook**, for the past 9 years Gardener to the Rev. G. H. Engleheart, Dinton, Salisbury, as Gardener to M. H. Beaufoy, Esq., Coombe House, Shaftesbury. (Thanks for 1s. for R.G.O.F. box.—Eds.)

Mr **F. Olver**, for the past 9 years Gardener to Lord Digby, Minterne, Cerne Abbas, Dorsetshire, as Gardener and Estate Manager to A. W. Page, Esq., Summernhill Park, Bath.

Mr. **E. E Thayer**, for the past 5½ years Gardener to Sir Richard Williams Bulkeley, Baron Hill, Beaumaris, Anglesey, as Gardener to E. C. Reed, Esq., Devizes Castle, Devizes, Wiltshire. (Thanks for 2s. for the R.G.O.F. box.—Eds.)

Mr **G. Bennett**, formerly for 10 years Gardener to W. G. Arkwright, Esq., Great Gravels, near Newbury, and previously for 10 years with J. Wyndham Smith, Esq., Aramstone, near Hereford, as Gardener to Lady Clarke Jervoise, Kirby House, near Hungerford. (Thanks for 1s. for R.G.O.F. box.—Eds.)

ANSWERS TO CORRESPONDENTS.

Fruiting of Cupressus funebris: *Beds.* Conifers in pots, and more especially Cupressus, Thuya, and Juniperus, often bear cones; there is, therefore, nothing unusual in your plants of Cupressus funebris coning. The cause of the occasional fertility of Conifers in pots is somewhat obscure, but it usually occurs with plants that are pot-bound or starved, and, if not accorded more generous treatment, the death of such plants may occur from exhaustion.

Grasses for Binding Land: *W. H. D.* The best of the grasses suitable for binding loose sandy areas is Psamma arenaria, the Marram grass. An article on sand-binding grasses was published in *Gard. Chron.*, October 2, 1909, p. 232.

Operations in the Rock Garden During Winter: *K. W. M.* During open weather in winter operations may be performed in the rock garden. An important work is top dressing the many plants that have grown out of the ground and made short stems. For this purpose use a compost of finely sifted loam, leaf-mould, and sharp sand. Work this material well in between the plants and growths, and it is especially valuable to such as are of tufted habit. For woolly-leaved plants, such as Androsaces, use more sharp sand and granite, or limestone chippings. Many plants that have grown too large or become crowded may be lifted and re-planted, renewing the soil in the process. If the soil is in the least degree stagnant or retentive, drainage in the form of broken bricks should be placed in the bottom of the hole and more sharp sand mixed with the soil. The re-building of the rock-work, where it is necessary, may also be done in winter, and this will permit of lifting all the plants and renewing or renovating the soil. During inclement weather labels may be overhauled, lists made of all indistinct ones on paper and fresh ones written under cover, ready for putting out in the spring. All dead stems and leaves should be cut away from the plants, and the whole place made tidy. Then put on the top dressing or mulch to take the place of dead leaves, in order that the plants may not be unduly exposed to the weather.

Shoddy as Manure: *J. C.* Shoddy by the truck load may be obtained from Messrs. Hollingshurst and Co., 112 Fenchurch Street, E.C. 3, and Messrs. Herbert Smith and Co., 9, Mincing Lane, E.C. 3. It is scarce at present, and there is usually some delay in delivery. The price varies according to the distance from the works.

THE CHRYSANTHEMUM IN CHINA.

I PROPOSE, for the benefit of those who may hereafter be interested in the literary or historical aspects of the Chrysanthemum, to place on record the existence of a most valuable paper which has apparently escaped the attention of all early European writers who have dealt with the subject.

It is noteworthy, in this respect, that it deals with the flower from a first-hand knowledge by an European author at a time many years prior to the introduction of the first large-flowering Chrysanthemum into Europe. The paper is of value because of the precision with which the writer describes the flower and its cultivation in China at a time when the object of his care was not even known as a Chrysanthemum.

The identification was brought about by the merest chance. Being latterly engaged in some researches in Chinese literature for details of the life and labours of that famous old Chinese Chrysanthemum grower and poet, T'ao Yuan Ming, I was led into an out-of-the-way channel from which much literary matter of peculiar interest was obtained. Considering the numerous writings about the Chrysanthemum, botanical and horticultural, which resulted from its introduction by Blancard in 1789, it does seem to me to be very curious that none of the authors that dealt with the newcomer for the first quarter of a century or so should have made any reference to the article about to be referred to.

It may be that the title of the article, even supposing our older writers ever came across the work in which it is contained, may have thrown them off the track, or it may be that the work was inaccessible, or not thought likely to be of service in connection with the subject.

The Chrysanthemum has been the victim so to speak, of considerable diversity of names. In the seventeenth and eighteenth centuries European botanists generally regarded it as a Matricaria. Breynius, Plunkenet, Kaempfer and others among the number. Philip Miller's historical curiosity (No. 2,412, anno 1764), referred to in the 8th Edition of his Dictionary, was described as Matricaria indica, although some authorities claim it as a small-flowering Chrysanthemum.

When Blancard introduced his novelty into France in 1789 it raised some discussion among French botanists. M. Ramatuelle, the first author to describe the plant from European-grown specimens, called it Anthemis grandiflora (see *Jour. d'Hist. Nat.*, 1792, p. 233). Although Ramatuelle considered the flower to be an Anthemis he admits (p. 246) that the name Matricaria had already been applied to it. Willdenow and Moench also gave it the same generic name, but differed in the specific. It seems useful to record these few facts superficially, in order that the reader may see how easily this old paper may have been overlooked, in a cursory search, even indeed if that were made.

Some of Ramatuelle's contemporaries considered Blancard's flower to be the Chrysanthemum indicum of Linnaeus's *Species Plantarum*, but he, and also Sabine later, rejected this idea, and the latter writer, after fully discussing the question, proposed the name C. sinense for the newcomer from the Far East, which had then begun to enjoy a great degree of popularity both in England and in France.

I now come to a fact which led me to alight upon this particular article. Many years ago, when the late Mr. Shirley Hibberd commissioned me to write the text for a special double number of *The Gardeners' Magazine* devoted exclusively to the Chrysanthemum, an old friend of mine in China sent me a quantity of valuable matter relating to the history and literature of the flower in that country. The Chinese name, or perhaps it would be more correct to say, the name for the Chrysanthemum in the province in which he laboured, is Chuhwa, and that name has ever since remained in my memory.

During my work I had occasion to consult Cordier's *Bibliotheca sinica*, in which there appears a reference to a French work dealing with the history, manners, etc., of the Chinese.

Cordier fortunately gives a list of many books on Chinese botany and allied subjects, and in his mention of the work just alluded to he briefly indicates the contents, which encouraged me to pursue still further my researches in that direction.

The book in question is one of a set of sixteen volumes, quarto, and bears the following title: *Memoires concernant l'histoire, les sciences, les arts, les moeurs, les usages, etc., des Chinois*. Par les Missionnaires de Pekin. 1ème troisième. Paris, 1778.

Much of the first part of this volume is taken up with accounts of the lives of celebrated Chinese emperors, statesmen, poets, and others—some with portraits. There is also an account of Chinese greenhouses. After this come notices of various plants, shrubs, etc., in China, and it was to this part that my especial attention was directed.

To the ordinary reader interested in the Chrysanthemum and possessing no knowledge of the Chinese vernacular there is but little in the chapter headings to suggest that there was anything about the Chrysanthemum therein.

These chapters bear the following titles: 1. Nenuphar de Chine. 2. Le Yu-kin. 3. Le Tsieou-hai-tang. 4. Le Mo-li-hoa. 5. Le Cha-tsiang-d'eau. 6. Le Lien-Kien ou Ki-teou. 7. Le Kin-hoa ou la Matricaire de Chine. 8. Le Mouton ou Pivoine. 9. Le Yé-hiang-hoa. 10. Le Pe-ge-long. 11. Le Jujubier. 12. Le Cheme. 13. Le Chataignier. 14. Les Oranges. Canges.

My eye lingered over No. 7. The name, as I involuntarily mumbled it, sounded strangely like Chu-hoa (Ch hard), and it is not making any pretence to a knowledge which I do not possess to say that anyone unfamiliar with the various systems of transliteration from the Chinese character into Roman can see that there was good reason for my assumption that these two names, differing as they do in spelling, might possibly mean one and the same thing, i.e., Chrysanthemum.

Again, the French writer, in giving the equivalent in his language, Matricaire, at once reminded me of the current appellation of the flower in those days immediately preceding the introduction of the Chrysanthemum into Europe.

What at first was a mere guess was soon proved to be the fact. The internal evidence in the article showed conclusively that the Kin-hoa was the Matricaria of our seventeenth and eighteenth century botanists, the Chrysanthemum indicum of the *Botanical Magazine*, the Anthemis of Ramatuelle, and the Chrysanthemum sinense of Sabine.

In the space at my command it is not possible to reproduce the article *in extenso*. The most I can hope to do is to draw attention to it and give in a condensed form just a few of its most salient features.

In its entirety this French Jesuit's treatise occupies seven or eight quarto pages, and it was evidently compiled by one of those missionary writers at least twenty-five years before Ramatuelle's description, for the simple reason that although Vol. III. of the *Memoires* bears upon its title-page the date 1778, we read on the last page, without a signature, "à Pé-King ce 3 novembre, 1767." Things moved slowly in those days, and the date of compilation and that of publication were separated by difficulty and delay in the journey between the two countries.

Now a few words about the article itself. The writer begins by telling us that the Kin-hoa, or Matricaria, is one of the most ancient plants known. It is, he says, mentioned in the Li-Ki of Confucius. I have not yet had time to look up a translation of that work, but I know second-hand that our Chrysanthemum is referred to in it by the great philosopher.

We learn also from this authority that in the first dynasty of the Tcheou (T'Chow) this Matricaria was represented in the embroidery on the garments of the Empress, the princesses and the principal ladies of the Court. If the herbarium attributed to Chin-nong is really of this Emperor, China has, says the writer, probably the first botanical book in which the flower is mentioned.

Regarding the popular superstition attaching to the Chrysanthemum, both in China and Japan, that a drink made from the Chrysanthemum ensures long life and preservation from evil, the writer tells us much about the same story concerning the Kin-hoa. A reference is also made to the native poets and their mentions of the flower.

It is curious from that point of view that up to now I can only make sure of one reference to the Chrysanthemum by Confucius. I have looked carefully through the Shi King, another of his books, and noted the flowers he speaks of there, but the Chrysanthemum finds no place in that book. On the contrary, later poets yield a little crop of references to this popular autumn flower, and I will mention just barely T'ao Yuan Ming (365-427 A.D.), who also bore the names of T'ao Ch'ien, and T'ao Tsien in Chinese and To-yem mei in Japanese; Tu Fu (712-770 A.D.), one of the greatest names among the Chinese poets; Po-chu-i (772-846 A.D.); and Sau K'ung T'u (834-903 A.D.), without coming further down the ages.

This old Jesuit missionary next proceeds to make comparisons with the Kin-hoa and some of the florists' flowers, notably the Auricula, which had then been much improved but which a century before was as little esteemed as the Kin-hoa or Matricaria.

He quotes Tournefort's description of the Matricaria and identifies the Kin-hoa with it. There are, according to the Chinese, two species—the cultivated and the wild. The cultivated ones are so numerous that they would require a long list to include all the kinds. He describes the foliage and the way in which it varies in different plants. As for the flowers, they are of so many colours and forms that to name them all would be a lengthy undertaking.

We have before us, continues the writer, a book printed at the Palace in which three hundred sorts are mentioned. How many have appeared since cannot be told—every year new ones are raised, and to know them all is quite a science.

The reader may almost say with me that this writer might actually be talking about the Chrysanthemum of the present day, and when

starts with but remark on cultivation the becomes still more apparent. He tells us that in China there are books on the culture of the Matricaria, just as in Europe there are some on Tulips, Carnations and other flowers. The requirements of the Kiku-hoa for successful culture are (1) an open position and fresh air which can be easily renewed. A narrow enclosure within four walls is a prison for this flower. The soil must be rich, well manured, prepared beforehand, and renewed every year. (2) The Kiku-hoa is propagated, firstly, by seed; secondly, by layers; thirdly, by grafting; fourthly, by suckers. These methods are then dealt with seriatim, and bear a strong resemblance to the directions of a twentieth-century European cultivator.

(3) When the Matricaria has done flowering, it is to be cut down to within 5 inches of the root, the soil stirred and manured, and as danger of frost approaches it must be covered with straw. As soon as the warmth of spring makes itself felt the plants are uncovered and watered, and they then throw out shoots; some florists leave only two or three of them and cut out all the rest; others take up the old stool entire and divide it into several parts, transplanting them in a soil prepared beforehand.

Briefly, the other directions are a reminder (4) that the Matricaria cannot stand too much dryness or too much wet. Rain or river water is best. Liquid manure as directed should be applied. Watering is to be done morning and evening, but the foliage should be moistened in the morning only. Too much strong sunshine is not good, but plenty of air is required. In the Emperor's gardens the plants have shelters made of matting to protect them.

The branches are liable to be broken by the winds; they should be tied to supports or stakes similar to those used in France for Carnations. Fifthly, only two stems are left on a plant; if others appear they are pinched out with the nail. Sixthly, amateurs leave but one bud on each stem; when it is as large as a Pea, manure water is given until it begins to open.

Then the writer goes on to tell us what the properties of the plant are, that the flowers last a month or more on the plant. The Emperor's apartments are decorated with this flower from mid-autumn to the end of winter. In a word, one might almost say that these cultural directions, instead of having been written in China nearly a couple of centuries ago, were compiled by one of our modern, successful, English cultivators less than a month ago, so closely do they approximate to our up-to-date cultivation.

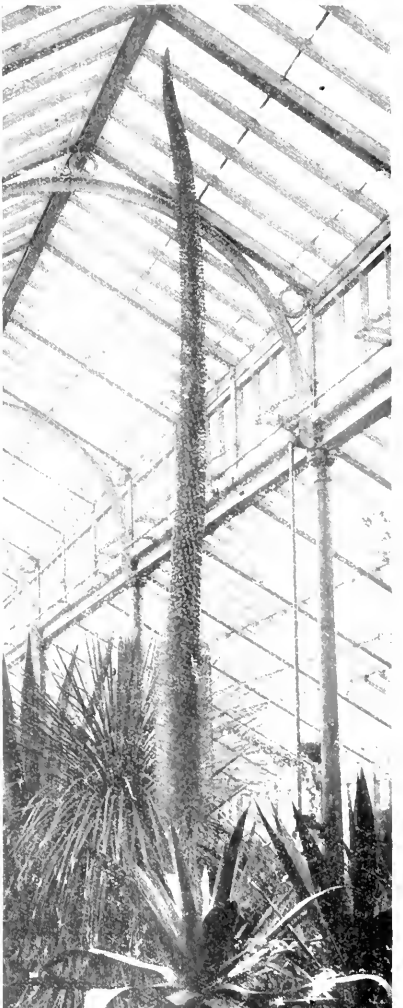
It is remarkable that while this exhaustive treatise lay hidden away in the pages of this old volume of *Memoires* the Chrysanthemum should have been introduced into Europe as a new plant, which it undoubtedly was, and that the growers had to learn by practice little by little the various details of cultivation which in the ultimate end so closely approaches that which the Chinese florists had long before adopted and which we Westerners might have imitated straightaway as soon as Blancard's introduction took place at the exhibition of the Chinese mode of culture so amply set forth in the treatise had then been widely made known.

Finally it is interesting to add that we are told that the flower enters into various decoctions in combination with Tea and gives its name to a blend which is used to form a compound pill.—*C. Harman Payne.*

TREES AND SHRUBS.

COTONEASTER ZABELII.

Of the many species of Cotoneaster which have been introduced from China during recent years C. Zabelii appears to me to deserve a high place in cultivation. It is most nearly allied to the European C. integerrima and C. tomentosa, but differs from them in having more numerous flowers in a cluster and in some other respects. The 4-10 flowers are followed by large, round or Pear-shaped fruits, one-third to half an inch long, of a crimson colour, and as the clusters are nodding or drooping on a fairly long peduncle they are highly conspicuous during the autumn and winter. As a wall shrub it would be more ornamental than C. Simonsii when in fruit, which is saying a good deal, seeing that the latter has found its way over most of Great Britain as a wall shrub, for planting in shrubberies or as isolated bushes. If C. Zabelii proves a success it may displace the old favourite for one purpose or another. Its leaves are linear and covered beneath with a yellowish grey felt, while those of C. Simonsii are paler beneath and merely hairy.—*J. F.*



[Photograph by C. P. Raffill.

FIG. 92.—AGAVE ELLEMEETIANA FLOWERING IN THE SUCCULENT HOUSE, KEW.

AGAVE ELLEMEETIANA.

AGAVES, as commonly known in gardens, have stiff leaves armed with formidable spines, and branched flower-spikes, the best known example being A. americana, popularly called the American Aloe. There are, however, a number of species with comparatively soft, unarmed leaves and flower-spikes of the bottle-brush pattern, and one of the largest of this group is A. Ellemeetiana, a Mexican species, first flowered in the Wilson Saunders' collection in 1867, and many a time since in other gardens. The illustration in fig. 92 shows a fine example of it in flower in the Succulent House at Kew, the spike nearly touching the roof, which is 15 feet high. The leaves are about 2 feet long and 6 inches wide, glaucous green, and of fleshy appearance. The flowers are arranged densely in pairs on the greater part of the spike, which is as rigid as a Larch pole, and they develop in bands after the manner of Kniphofias. They are yellow-green. The plant is monocarpic; that is, it dies after once flowering, but it sets seeds freely, and is therefore easily preserved. At Kew this Agave flowers when it is about twenty years old. These soft-leaved species are less hardy than A. americana, and they are liable to injury, as they are awkward to move and are easily bruised. Another species of the same group, and not unlike A. Ellemeetiana is A. attenuata, but it has a nodding, not erect, flower-spike, and is remarkable in developing a long, woody stem before it flowers and dies.

ON INCREASED FOOD PRODUCTION.

POTATO KING GEORGE.

THE variety King George is one of the best second early Potatos, and is immune to Wart Disease. It is a white, oval, kidney sort, and has few equals in cropping. By planting sprouted tubers early the crop may be lifted in time to plant Leeks, Savoys, and other Greens, and it keeps good until March. I find it good practice to plant second earlies such as King George and Great Scott and lift them in August before late blight becomes troublesome. *Japonica.*

ELECTRIFIED SEED.

MR. W. GUY has grown on an allotment near Parkstone, Dorsetshire, a row of Savoys of enormous dimensions from electrified seed. One plant measured 4 feet 1 inch across, weighed 13½ lbs., and one of the outer leaves measured 24 inches in length and 20 inches in breadth. The plants in the adjoining rows were grown from unelectrified seed and were of ordinary dimensions, weighing between 2 lbs. and 3 lbs. each. *Dr. Morton, Moorcroft, Parkstone.*

VEGETABLE MARROW GROWING.

THE Food Production Department states that a grower in Berkshire who had 6 acres of land on which he could have planted nothing else this year responded to the invitation of the authorities to grow Vegetable Marrows by sowing this area with Marrow seed. It produced 24 tons 3 cwt., and he sold the crop through the Berkshire Fruit and Vegetable Society—which works under the F.P.D. Scheme for marketing surplus produce—for £144.

TENURE OF ALLOTMENTS.

IT is found that many holders of allotments under the Cultivation of Lands Orders are still in doubt as to the period for which they hold their plots. In order to make the position clear the Food Production Department has issued the following statement on the subject. As the result of recent legislation (the Corn Production (Amendment) Act, 1918 (Section 1)) allotment holders under the Cultivation of Lands Orders are now secure in the occupation of their plots until the expiration of two years from the "termination of the present war" (which term has to be defined by Parliament) except in those

cases where it is shown to the satisfaction of the Board that the land is required earlier for building or other special purposes, or where the compensation payable if the land is retained would be in excess of the value to the nation of the food produced. If, owing to the land being required for one or other of the above-mentioned purposes, any such allottee has to surrender his plot before January 1, 1920, he will be compensated by the Board of Agriculture for the growing crops, etc.

Powers conferred by the Small Holdings and Allotments Act, 1908, however, provide the means of securing longer periods of possession for those allotment holders under the Cultivation of Lands Order whose land is not required for the purposes already specified. Those powers enable Local Allotment Authorities in agreement with owners to take allotment land for long leases.

ONIONS ON PLOUGHED GRASS LAND.

I NOTE, in your article on "Ploughed-up Grass Land," that you advise planting Onions on such land, and that they have proved a success. I would advise those who contemplate planting lea ground with Onions in the coming year to first ascertain if wireworms are present in the soil. Last spring I planted 5½ acres of lea ground with Onions and lost nearly every plant; the wireworms destroyed them wholesale, notwithstanding that the ground received a good dressing of soot and salt. *G. Meiklejohn, Ohey Lee Gardens, Queen's County.*

PEAS UNDER GLASS.

THE present month is a suitable time to make the first sowing of Peas either in pots, boxes or borders. For sowing in borders I prefer the varieties Duke of York, Duke of Albany, and Royal Warrant; when sown in the open these varieties attain to a height of about 5 feet, but when sown in pots they seldom grow taller than 4 feet. Chelsea Rival and Little Marvel are suitable for growing in pots and boxes in low houses. Peas grow well in fibrous loam mixed with manure from a spent Mushroom bed. The pots should be 10 inches in diameter, and well drained. They should be three parts filled with soil, and 12 sound seeds will be sufficient in each pot. Cover the seeds with 1½ inch of soil and then well water the soil. Guard against mice and slugs. When the plants are about 3 inches high they should be thinned to six of the strongest. At that stage top dress the roots with some of the soil used for sowing. Tie each plant to a neat stick and, as growth develops, give further support. Remove all side growths, but one must judge by the variety before the points of the main growths are removed. Admit air freely, and use fire-heat only in times of severe frosts. Failure is sure to follow should the soil be allowed to get dry. When the pods start to form the use of diluted liquid manure at every alternate watering will prove very beneficial to the plants. Close the house in the afternoons to hasten the swelling of the pods. An additional sowing should be made in January in pots and the plants grown on in pots; by the time the plants of this late sowing are bearing pods early Peas on south borders will be making considerable headway. *C. Davis, Holy Well Park Gardens, Ipswich.*

POTATO MAJESTIC.

I PLANTED on May 6 last one cwt. of seed tubers of Majestic Potato, and the plants were grown in ordinary field conditions. The yield was 40 cwts. of clean, healthy tubers, with about one quarter of the total seed size, and no small ones. The seed was supplied to me "as grown," which was in accordance with the Government Potato Order, and was by no means a good sample. It can, therefore, be easily understood that if the tubers had all been of proper seed size the quantity purchased would have planted a wider area, with a correspondingly greater yield. *John Robertson, Bellefield Gardens, Lanark.*

SOME OF THE NEWER ROSES.

OLDER ROSES OF 1918.

CONSTANCE (Perpet. Duchet). A sport of Ye's Austrian Briar Hybrid, and a better grower than Rayon d'Or, though not always; not so full nor so deep in colour.

MERRY DICKSON (H. Dickson). A grand garden Rose. Austrian Briar Hybrid; extra ordinarily thorny, with large, rather loose, nearly full blooms. Well worth growing, and succeeds best where it does not get early sun.

NAIAD (G. Paul). Erect, passing to pinkish white. Large, only semi-double, but very fine when open, and shows the abundant anthers. An Austrian Briar Hybrid.

ROSES INTRODUCED IN 1918.

The following are Hybrid Teas only:

CHARLES GOODWIN (A. Dickson). A fine and free-blooming Rose, pale cream, deeper in the centre, of very fine shape and good size; very beautiful.

CLEVELAND (H. Dickson). Another good variety; the blooms show a mixture of colours, and possibly it is some relation to that fine Rose Gorgeous; a reddish copper tone with yellow at the base. Fairly vigorous, of fine shape and size and full.

CRIMSON CHATENAY (Merryweather). A crimson seedling from Mme. Abel Chatenay, though one might not suspect it; of good colour and growth, and likely to be a fine decorative Rose.

DONALD MACDONALD (A. Dickson). A very

FLAME OF FIRE (McGredy).

fine Rose, one of the best rich crimsons, with dark anthers; vigorous and free.

ECLIPSE (B. R. Cant). A very attractive climbing sport, very large blooms, in a warm shade of peach and pink, produced in clusters. A Pillar Rose.

LEMON PILLAR (G. Paul). This climber I have seen from its early stages. At first pruned hard, it was not free, but is now free on a pillar. It is a Hybrid Noisette, much resembling Marechal Niel (one of its parents) but paler, large, full and good. A distinct gain, and will probably be the parent of other good Roses.

PRINCE MARY (Hobbies). A fine full Hybrid Tea Rose, one of the best rich crimsons, with dark anthers; vigorous and free.

QUEEN (B. R. Cant). A very attractive climbing sport, very large blooms, in a warm shade of peach and pink, produced in clusters. A Pillar Rose.

LEMON PILLAR (G. Paul). This climber I have seen from its early stages. At first pruned hard, it was not free, but is now free on a pillar. It is a Hybrid Noisette, much resembling Mme. Marechal Niel (one of its parents) but paler, large, full and good. A distinct gain, and will probably be the parent of other good Roses.

FLAME OF FIRE (McGredy). Probably one of the best decorative Roses we have (see fig. 94), like a glorified Mme. E. Herriot. Strongly recommended, though at present I am not sure as to its growth. I think it is "fairly vigorous." Orange flame in colour.

FLORENCE SPAULL (B. R. Cant). Rosy pink in improved Helen Keller; large and full; very promising.

HENRIETTA (Merryweather). A rodless Rose, fairly full, orange-crimson. Free, a good grower, and holds its head up better than Mme. E. Herriot. A bedding variety.

FIG. 94.—FLAME OF FIRE.

HON MRS R. C GROSVENOR (B. Cant). Colour, pale flesh, centre orange. A garden Rose of fair size, free, pretty, but not very full.

MRS. A. GLEN KIDSTON (A Dickson).—A very pretty bedding Rose, of mixed colouring, becoming deep rose; free and well formed.

MRS. BRYCE ALLAN (A Dickson and Sons).—An exhibition Rose of fine type; carmine-rose, erect, highly scented, and very promising.

MRS. DUNLOP BEST (Hicks). Reddish-apricot and yellow; very pretty colouring. A good garden Rose, and apparently free from mildew.

MRS. A. W. ATKINSON (Chaplin). — Ivory-white, large, full, pointed, and with very thick petals. Has stiff, strong wood, is fairly vigorous, looks like a cross between Frau Karl Druschki and Marchioness of Londonderry. I consider it was worthy of a Gold Medal in 1916.

MRS. CHAPLIN (Chaplin).—A Rose similar to Mrs A. W. Atkinson, but with a little pink in it; a fine exhibition variety.

FIG. 94.—ROSE NELLIE PARKER. COLOUR CREAMY YELLOW, DEEPER YELLOW IN THE CENTRE.

MRS. MONA HUNTING (Hugh Dickson).—A delightful garden Rose, not quite large enough for show purposes, and might have greater length of petal. It is a chamois-yellow, paling somewhat as it opens. Quite full, opens well.

NELLIE PARKER (H Dickson) (see fig. 94).—One of the best Roses. A grand, full bloom of fine shape, a fairly good grower (perhaps more than that), free, and every bloom seems to come good. Colour, creamy-yellow, deeper yellow in centre, and sometimes flushed with pink.

PRINCE CHARMING (H Dickson). A bedding Rose, almost single, and I have placed my plant among the singles. Reddish colour on old gold; free, and lovely in the bud.

MODESTY (McGredy).—A grand Rose, either for garden or show purposes, and a good grower. The colour is creamy-white flushed with deep pink. The bloom lasts very well either on the plant or when cut and the stem placed in water.

RED CROSS (A Dickson and Sons).—A striking Rose, and useful; erect, fine crimson colour, free, and vigorous; a fine bedder.

TIPPERARY (McGredy).—A yellow garden Rose, of exceptional freedom. It promises to be most useful for bedding.

W. C. GARNT (A Dickson and Sons).—Bright scarlet, with the backs of the petals crimson maroon; fairly vigorous, of fine shape and medium size; very branching and free. A good garden Rose.

OTHER ROSES OF 1916.

CLIMBING IRISH FIREFLAME (A Dickson and Sons).—Like the beautiful original, but a climber.

ISOBEL (McGredy).—One of the best singles, and very distinct. It is described as carmine-red, flushed orange scarlet, but with me it has had lovely flowers of a rosy red tone, beautifully shaded, with centre yellow. A good grower, free and attractive.

QUEEN OF THE BELGIANS (Hicks). Rich salmon-pink and very free; a colour wanted in the singles; very pretty.

ULSTER GEM (H Dickson).—Yellow, free and good. Like many yellow roses, it pales as the flower ages. Quite a fair grower and striking.

PAUL'S SCARLET CLIMBER (W. Paul).—Undoubtedly one of the best Hybrid Wichuraianas; bright scarlet, shaded crimson; free, very lasting and good. Perhaps not so wildly vigorous as some Wichuraianas.

SILVER GEM (G Paul). — A lovely, rose-coloured, almost single, dwarf Polyanthus Rose, with paler eye. Foliage variegated; very distinct and good. *L. C. B. Norris Elgie, Ufford Manor, Louth, Lincolnshire.*

(To be concluded.)

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Broccoli.—In many districts there is the greatest difficulty in wintering Broccoli, no matter how carefully the plants and ground have been prepared. Placing the heads of the plants near the ground and facing them to the north is the simplest way out of the difficulty, as few need to be told that the stems of Broccoli are most susceptible of injury from frosts. Open a rather deep, sloping trench on the north side and then, with the help of a spade inserted well behind the plants, carefully place them in an oblique position with the heads facing north. The roots should not be disturbed more than is necessary. Cover the roots with soil made rather firm and lightly cover the stems with soil. The next row of plants should then be laid over, and so on, until the whole are finished. If the work is done carefully in fine weather the plants will receive no great check to growth.

Cabbages.—Hoe the soil, whenever the work is possible, between the rows of autumn-planted Cabbages, whether weeds are present or not. Hoeing keeps the ground sweet, and allows the air to penetrate freely to the roots. It also stimulates growth, and protects the stems of the Cabbages from injury by severe frosts.

Seasonable Remarks.—Heavy land should not be trampled on when it is wet from rain or in a moist state after a thaw, as when in this condition soil binds readily. The rougher clayey land is dug in autumn and winter the easier will frost penetrate to a good depth. Sharp hoar frosts lead us to expect severe black frosts, which generally last longer, and are much more penetrating. Bracken and garden mats should be ready at hand for covering salad plants and other vegetables that hard frosts would injure. Examining Onions and Potatos in store will provide work for the staff indoors during wet weather. Every care should be taken of seed tubers intended for planting next season. Home-saved seeds of Peas, Beans, and other vegetables should be sorted, and all unsound ones discarded. Beans especially were late in ripening, and should be thoroughly dried before being stored.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Miltonia.—Plants of Miltonia vexillaria, M. Bleuana, and their hybrids, are growing steadily. As the roots are now very active the compost should not be allowed to become very dry, but sufficient water afforded it to keep the Sphagnum moss on the surface alive and fresh. These growing plants will need constant attention, as the young leaves frequently adhere to each other so firmly that they soon become crumpled if not carefully separated, which is best done by means of the thin end of the handle of a budding knife. A brown, damp-looking, outer sheath at the base of the young growth often clasps the stem so tightly that the roots push upwards inside it instead of growing into the compost. This sheath should be removed in pieces without causing injury to the plant. The leaves sometimes show signs of damping at their tips at this time of the year; this defect is best obviated by keeping the roots a trifle drier, having a slightly drier atmosphere and affording a little extra ventilation. Plants of M. v. Leopoldii and M. v. superba that have recently passed out of flower should be repotted, if this operation is necessary, when the young growths commence to send out new roots from their bases. The hybrids M. Bleuana and M. Hyeana, which are irregular in their season of flowering, may be dealt with in a similar manner. Should cold weather necessitate the use of more fire-heat, keep a careful watch for yellow thrip and other insect pests, and, as a precaution, dip the leaves and growths in an insecticide at least once every two weeks.

Dendrobium.—Plants of Dendrobium Wardianum, D. crassinode, D. aureum, D. nobile and their numerous hybrids that are developing flower-buds may be removed from their resting quarters into a house where the temperature does not fall below 55°. If no other structure is available the Cattleya house will suffice until the buds are nearly developed, when the plants may be placed in a light position in the warmest division. At present only sufficient water should be applied to the roots to keep the pseudo-bulbs plump, as over-watering and high temperature while the blossom buds are developing is conducive to irregular flowering. Growth will be very slow at this season, and the object should be to encourage the buds to develop without causing growth to start at the base of the plant. Where numbers of plants of D. nobile are grown, the flowering period may be extended over several months by placing the earliest specimens in a cool, dry house to rest, and as soon as the growths are matured, bringing a few plants into a warmer house at intervals. The bulk of Dendrobiums will flower in the spring, and these plants should remain in their resting quarters until the flower buds are apparent. Such late flowering Dendrobiums as D. Parishii, D. Bensoniae, and D. superbum having completed their current season's growth, should be placed near the roof-glass in the Cattleya house during their resting season.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Coleus thyrsoideus. This winter-flowering stove plant has been grown here in much cooler conditions than is usually recommended. The only apparent difference is that the plants are much dwarfer than usual. It is now coming into flower, and a drier atmosphere will be maintained to counteract the cooler conditions. Now that growth has practically ceased water must be applied with extra care. A little stimulant used about once a week will meet all requirements in this respect. A little air should be admitted to the house whenever the weather is favourable, and, with careful attention to cultural details, the plants will continue to flower all through the winter.

Hippeastrum (Amaryllis). Select a few of the most promising bulbs of Hippeastrum for placing in the forcing house. Remove an inch or two of the old surface soil and apply a top dressing of rich material, such as a mixture of fibrous loam, leaf mould, crushed bones, and sand. Examine the drainage and see that it is perfect, as it is essential that surplus water should pass away freely.

Gardenia. Let plants of Gardenia which are forming their flower-buds have liquid manure from the farmyard, or, failing this, a concentrated fertiliser. It nearly long is troublesome, take measures to destroy the pest before the blooms begin to expand or many of the trusses will be spoilt. It is an excellent plan to lay the plants on their sides and vigorously syringe them with an insecticide; if this be done once a week the plants will be kept clean. A minimum temperature of 55° should be maintained while the flowers are developing.

Chrysanthemums. If plenty of good cuttings are available a large batch of Chrysanthemums should be propagated at once, and the old stools discarded. It will save labour if cuttings of the decorative varieties are inserted in ordinary cutting boxes. Use an open, sandy compost, and see that it is made quite firm in the boxes before inserting the cuttings. The shoots will root readily in a propagating case, which may be placed on the stage of a greenhouse. When rooted, grow the plants near the roof-glass in a cool house.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Birds and Fruit Buds. From observations extending over several years I have noted that the amount of injury done to fruit buds by birds differs in extent in different years. The degree depends, doubtless, upon the amount of food the birds are able to obtain. Sparrows are more destructive to Red and White Currants and to Gooseberries than any other birds; at least, that is my opinion. After a sudden fall of snow, and whilst this still lies upon the ground, the birds are unable to find food in the soil, and it is at such times that some birds devour the buds of fruit trees. The best deterrent to the house-sparrow is black thread strung from bough to bough as soon as the bushes have been pruned. Where these fruits are trained against walls, old pieces of garden netting serve the same purpose admirably. Birds of the finch tribe are more disposed to attack the buds of Plums than those of any other fruits. The gun has to be used in extreme cases, although I am very reluctant to destroy birds by shooting them. Black thread may be used for these bigger trees also; the reel of thread should be thrown over the tree from side to side, and with two operators this work will be considerably expedited. In bad cases of bird attacks the fruit quarters that have provision for protecting the bushes by nets arranged so as to make a kind of cage may have the nets placed in position, but this should not be done unless other means have failed, for the birds destroy many insect pests. I have never observed any harm to Cherry trees, on the contrary, birds find a large amount of insect food in those trees. I never destroy birds' nests.

Nailing and Tying Wall Trees. Let the work of nailing and tying the shoots of wall fruit trees be hastened as speedily as possible while mild weather continues. Of the two, I think nailing is a more pleasant operation than tying. Where shoots are scarce an excellent substitute may be found in the young, slender tops of the Willow. A little practice is needed, but after a time the work may be accomplished fairly easily; this method takes the place of shreds to a safer degree than does the use of tarred string. Old shreds harbour insects; not so the Willow tips, whilst these latter will in due time decay and not do any harm to the branches. Keep a close watch for any old ties that may be so tight as to compress the bark, which, in the case of such fruits as Cherries, might cause gumming. In the case of wires, any undue pressure against the shoots must be eased by placing suitable material between the bark and the wire.

Raspberries and Similar Fruits. The final thinning of the canes of summer fruiting Raspberries should be attended to before the end of the present month. Leave the strongest shoots the longest when they are tied, shorten those of medium length half way, and cut the weakest canes still harder. In this way it is possible to make the best use of the available space. If there are no facilities or time for training the shoots in this way they may be simply tied together without any stakes, as is done in market gardens. Do not attend to the autumn fruiting Raspberries until the spring. Get the pruning of all Gooseberries, even on the cordon system, out of hand and the plants tied. If the presence of American Gooseberry mildew is suspected, spray the bushes with lime sulphur when the work of pruning and training is finished. Brambles of the Loganberry section should be pruned and tied before a fall of snow impedes the work.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

Propagating Vines. If young canes are required for planting next year, select the best ripened prunings from the strongest and healthiest vines for propagating. Undoubtedly the best method of increasing the Grape Vine is by "eyes" inserted in small pots in January. In the meantime, tie the prunings in small bunches labelled with the name of the variety, and heel the cuttings in on a south border.

Propagating Figs. Figs may be increased from well-ripened buds in the same manner as Vine eyes, or by cuttings 3 or 4 inches long made from well-ripened shoots. The former make plants with clean, straight stems the first season, and Figs propagated in this manner may be grown as miniature standards. By adopting the latter method, smaller, but more compact bushes are formed. The shoots for cuttings should be selected when pruning the trees and inserted in a cold frame until January.

Early Strawberries. With carefully prepared plants it is possible to obtain ripe Strawberries very early in the season, although it is not advisable to attempt this on a large scale, for, with little or no sun early in the year the fruits lack flavour. Far better results are obtained by starting the plants another month or even six weeks hence. For very early forcing the pots should not exceed 5 inches in diameter, the plants should possess a ball of healthy roots, and have firm, well-ripened crowns. If a suitable forcing house is not available, a sharp pitched Melon pit fitted with narrow shelves at a distance from the roof-glass sufficient to allow the plants space when they are in flower, offers a good substitute. A bed of leaves and stable litter should be placed under the shelves, turning and renovating the materials at intervals as occasion demands. Some growers plunge the pots in the fermenting material, but directly the flower spikes appear the plants should be placed on a shelf near the roof-glass, as an excess of bottom heat encourages the development of soft, elongated leaves and weak flower stems. Before the plants are introduced to the forcing house the pots should be washed, the drainage examined to ensure a free passage of water, and all decayed foliage removed. Strawberries grown under glass are very liable to attacks of mildew and red spider, and for this reason it is advisable to dip the plants in sulphur water. Maintain a temperature of 40° to 45° at night and 50° by day. No hard-and-fast rule can be laid down in this respect, as it sometimes happens that 40° or more at night may be followed by 55° or 60° for a few hours on mild days. Careful attention in watering with tepid water is essential, for at this early stage there is a risk of giving too much moisture, whilst drought at the roots would be equally injurious.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

Lawns. Take advantage of a fine day or two to give the lawns a final clean up for the year. Even the latest Oaks should have shed their leaves by now, and with the leaves there will be bits of stick and various other unsightly objects gathered since the previous general cleaning. If time permits imperfect parts of the turf may have a slight dressing of old compost sprinkled upon them. The material will get washed in very soon, and the evidence of its having been applied is not seen till spring, when denser vegetation appears. It also saves labour to apply it now instead of in spring, when gardeners, it is clear, will be busier than they have ever been.

Pampas Grass. Large clumps of Pampas Grass, which is not quite hardy, are very handsome on broad lawns. This year the spikes were not produced till well into November, owing to the freezing of the plants last winter. The value of the plumes for decoration is well known, and where they are required for this purpose they should be cut at once, being careful that the hands are not cut by the deeply serrated edges of the leaves in doing so. Both this grass and Tritomas of kinds, where winters are usually severe, should have littery straw drawn over and around the stools which, notwithstanding that the leaves may be destroyed by frost, retain enough vitality to make good growth and produce flowers the same year. The litter from stables possesses a certain amount of manurial value and the food will be washed down to the roots by rain and melting snow.

Protecting Iris Susiana and Other Tender Plants. Iris Susiana is developing new growth, and though it is hardy at least, in ordinary winters it is of much advantage to its well being to shake some manure among the shoots. Similar treatment should be accorded to Belladonna Lilies, first stirring the surface of the ground around the latter previous to applying the manure. The brilliant spikes of Schizostylis coccinea stand as a reminder that in many gardens it is important to throw some protecting material among the plants. Myosotidium nobile I find can only be protected properly here by placing something clear of the foliage, which is so easily damaged. Double scrim is suitable.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations. *The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Local News. *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS 41, Wellington Street, Covent Garden, London**. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38.5°.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, December 11, 10 a.m. Bar. 30·, temp. 52° Weather Dull.

Self-Sterility in Fruit Trees.

The practical importance of obtaining full knowledge of the self-sterility or self-fertility of different kinds of fruit trees is recognised by all fruit growers, and hence the results of the researches into this subject which have been carried on for some years past at the John Innes Horticultural Institution are to be welcomed, not only by the scientific student, but also by the grower. A summary of these researches begun by Mr. Backhouse and continued by other workers at the Institution, is now published* by Miss Ida Sutton, who since 1915 has been carrying on the work.

The researches which have been made on Plums, Cherries, and Apples show that in each of these fruits there are three categories of varieties, namely, those which are self-fertile, those which are self-sterile, and those which are partly self-fertile. The varieties which have been tested at the John Innes Institution are given below in the classified list.

PLUMS.

SELF-STERILE.	PARTLY SELF-FERTILE.	SELF-FERTILE.
Coe's Golden Drop	Rivers' Early Prolific	Denniston Superb
Coe's Violet	Early Favourite	Early Transparent
Crimson Drop	Coe's Emperor	Reine Claude Violette
Jefferson	Early Orleans	Golden Transparent
Bryanston Gage	Cardinal Dawson	Reine Claude de Bavay
McLaughlin's Gage		Oullin's Golden Gage
Early Green Gage		Reine Claude d'Althan
Old Green Gage		Monarch
Reine Claude d'Althan		Prince Engelbert
Pond's Seedling		Prune Gesunte
Wyedale		Gisborne
Frogmore Orleans		Victoria
Late Orleans		Czar
Prune d'Agen		Pershore
Primate (small numbers of flowers selfed, but no other cross on tree)		Yellow Magnum Bonum
Frogmore Damson		Early Mirabelle
		Myrobalan Red
		Belgian Purple

CHERRIES.

SELF-STERILE.	PARTLY SELF-FERTILE.	SELF-FERTILE.
Amber Heart	May Duke	Flemish Red
Black Eagle	Archduke	Late Duke
Black Heart		Morello
Black Tartarian		
Bigarreau de Schreken		
,, Noircie Gubert		
,, Napoleon		
,, Jaboulay		
,, Frogmore Early		
Early Rivers		
Elton		
Governor Wood		
Guigne d'Annonay		
Kentish Red		
Toussaint		
Waterloo		
White Heart		

APPLES.

SELF-STERILE.	PARTLY SELF-FERTILE.	SELF-FERTILE.
Beauty of Bath	Worcester Pearmain	Antonowka
Cox's Orange Pippin	Bramley's Seedling	Annie Elizabeth
Gascoyne's Scarlet	Lord Hindlip	Baldwin
Lane's Prince Albert	Lady Sudeley	Cellini Pippin
Norfolk Beauty	Old English Broadleaf	Coronation
Northern Greening	Doucin	Duchess of Oldenburg
Grime's Golden	Improved Doucin	Golden Spire
Yellow Newtown (very small number of flowers selfed)	Pyrus prunifolia	King of the Pippins
	P. baccata	Lord Derby
	Golden Russet	Red Winter Reinette
		Ribston Pippin
		Stirling Castle
		Sturmer Pippin
		Washington
		French Paradise
		Crimson Bramley

Although the author is properly cautious with respect to general conclusions, it appears fairly certain from the evidence which she adduces that, with one exception, self-sterile varieties show themselves fertile with the pollen of all other varieties. If this be so, it follows that there is no need for making experimental search for suitable pollenisers: any variety whose flowers bear plenty of pollen, provided it flowers simultaneously with the variety to be pollinated, will do for planting among self-sterile varieties. This to the fruit grower is welcome news.

The only exception is that of the Plums Coe's Golden Drop, Crimson Drop, Coe's Violet and Jefferson. These varieties are apparently incompatible: that is to say, they will not serve as pollenisers of one another. As the author points out, this case is specially interesting in view of the fact that Crimson Drop and Coe's Violet are known to be bud-sports of Golden Drop and Jefferson is suspected of similar origin. Hence they are all one except for the sporting character, and therefore there is nothing surprising in the fact that the self-sterility of the original shows itself in sterility between the original and its sports.

The existence of the three categories, self-sterile, self-fertile, and partly self-fertile, is not inconsistent with the hypothesis that self-sterility is a recessive character, although on that view it might be expected perhaps that self-sterile varieties should be self-sterile with one another. But our knowledge of the physiology of fertilisation does not justify our taking *a priori* views, and it is to be hoped that the study of subsequent generations of plants raised by crossing self-sterile and self-fertile varieties may settle this point ultimately.

It should be added that although in the case of Plums any polleniser will apparently serve to render fertile any self-sterile variety, in the case of Cherries the evidence is not so clear. In some Cherry crosses the number of fruits obtained is so small as to suggest incompatibility. For example, Bigarreau Frogmore Early set no fruit in 80 tests made by pollinating it with Late Duke, and none in 63 tests made with Bigarreau de Schrecken as the pollen parent. Indeed, an inspection of the most extremely valuable table recording the results of the numerous experiments seems to suggest that something very like incompatibility does exist in Cherries; that is, that certain varieties only are efficient as pollenisers. Yet it has to be remembered that pollination is often chancy work even when carried out with the utmost care—and hence on this important point we must await the results of further investigation.

* *Journal of Genetics* VII., 4, August, 1918.

Our Almanac. — We shall be obliged if secretaries of horticultural, botanical, and allied societies will send us immediate information of all shows and other fixtures for the coming year, for insertion in our Annual Almanac for 1919.

R.H.S. Fortnightly Meetings, 1919. — The following dates have been fixed by the Council of the Royal Horticultural Society for the fortnightly meetings during 1919, to be held in the Drill Hall of the London Scottish Regiment, Buckingham Gate, Westminster: January 14, 28; February 11, 25; March 11, 25; April 8, 29; May 13, 27; June 17; July 1, 15, 29; August 12, 26; September 9, 23; October 7, 21; November 4, 18; December 2.

Small Holdings for Germans. A statement published by Field Marshal VON HINDENBURG says that preparations are in hand for the purchase of 100,000 small holdings from the public funds to be transferred cheaply to farmers, gardeners, and artizans. For town workers, employees, officials, and the like, garden cities are to be built, where the houses will be rented at a moderate rate of interest on the cost of construction. The statement concludes with an appeal to the soldiers to save the German Fatherland by German discipline and German sense of order, and thus to prepare their own future happiness.

The Root Crops. The preliminary statement of the Board of Agriculture on the produce of the root crops shows that the yield of Potatos this year, 6·6 tons per acre, is equal to that of last year, and one-third of a ton above the average. The total production amounts to 4,209,000 tons, by far the largest ever raised, and 863,000 tons, or more than 25 per cent., above last year's record. Turnips and Swedes show a yield just over the average, 13·2 tons per acre, and more than half a-ton above last year; the total production, however, owing to the reduced acreage, amounts to 12,018,000 tons, and is a little below last year's total. Mangolds, with 20·6 tons per acre, are about 1 ton above the average, but 1½ tons below last year; the total production amounts to 8,231,000 tons, which, although a quarter of a million tons less than in 1917, is, apart from last year, the highest since 1912.

Plant Immigrants.—*Plant Immigrants*, No. 140, contains a brief description of the Benguet Lily, Lilium philippinense of Momba. This species of white trumpet Lily is said to be destined to become of great value both to commercial and private growers, and to be specially noteworthy for the shortness of time between potting and flowering. L. philippinense bears long, pure white, sweet-scented flowers on strong stems with graceful foliage. This species was first described by Mr. J. G. BAKER in *Gard. Chron.*, August 23, 1873, and was illustrated in the same issue (fig. 243).

A New Source of Alcohol.—In a recent communication to the French Association of Che-

nists of Sugar refinery and Distillery, Mr. H. COLIN, professor at the Catholic Institute, Paris mentions Anthriscus sylvestris as a possible source of alcohol in present conditions. The root of this plant, which is very abundant in parts, in fields and woods, contains a considerable quantity of crystallisable sugar and starch. Mr. COLIN obtained the following results from 100 grammes of fresh material: Reducible sugar, 0 gr. 96; saccharose, 5 gr. 64; starch, 14 gr. 50. The root also contains an active principle having a strong and disagreeable smell, but the author was able to assure himself that the principle is in no way poisonous, and that in any event it would not hinder the development of yeast when fermenting. The plant is biennial, and it would therefore be at the end of the first year of growth that the roots should be collected. At Verrières, Anthriscus sylvestris has formed the subject of an interesting experiment in selection, which, begun in 1874, is still progressing. This experiment was set on foot by HENRY DE VILMORIN, with the aim of replying to certain objections made to the efforts of his grandfather to ameliorate the wild Carrot.

An Agricultural University as Proposed Peace Memorial. A proposal to connect Vale Peace by establishing a Lincolnshire University emanates from the Rev. H. COLTON SMITH, vicar of Bourne. It is suggested that such a university should be established at Grantham or Spalding in the special interest of scientific agriculture.

Retirement of Mr. J. H. Goodacre. After a very long period as head gardener at Elvaston Castle, Derby, the veteran Mr. J. H. Goodacre is retiring from active service and a wide circle of friends will join heartily in the wish that he may enjoy many years of health and happiness. Mr. J. H. GOODACRE has had charge of one of the and famous gardens, and one of the few where topiary is still a great feature. As a skilful cultivator and exhibitor of both hardy and indoor fruits he has been to the front rank of successful competitors at London, Shrewsbury and other shows, for many years. He is to be succeeded by his son, Mr. B. GOODACRE, who now becomes gardener to the Earl of HARRINGTON, at Elvaston Castle, after twelve years' service as gardener to Sir E. CASSEL, at Moulton Paddocks, Newmarket.

"Punch" Almanac for 1919. The most features of Mr. Punch's Almanac for 1919 are topical, and both illustrations and text are calculated to produce that tonic effect so desirable at the close of an influenza epidemic. "If Parliament Were Called Up" is a delightful double page illustration, in which, among other things, Mr. PROTHERO is depicted hastily tuning up the camp allotment. The beauty of the Almanac is that its humour appeals to everyone in general, and to practically everyone in particular; for instance, the illustrated ode on Watering Roses and the one on Intensive Lessons on the Land will evoke hearty understanding laughter from horticulturists, now that the world has learned to laugh again. Mr. RAVEN HILL'S cartoon of the war-scarred 1913 handing on the torch of victory to the vigorous young 1919 is a fine conclusion to the Almanac.

War Horticultural Relief Fund. The Lord Mayor will preside at a meeting, to be held at the Mansion House on December 18, in support of the Royal Horticultural Society's War Horticultural Relief Fund. The principal speakers announced are Lord GRENFELL (President, R.H.S.), Col. Lord BURNHAM, The SPEAKER, Lady NORTHCOTE, Col. Sir CHAS. C. WAKEFIELD, and Sir HARRY J. VEITCH, hon. treasurer of the Fund. The meeting will commence at 3 p.m., and the Serbian Choir will be in attendance from 3 to 3.30 p.m.

New Garden Superintendent at the John Innes Horticultural Institute. We learn that Mr. A. HOSKINS has been appointed superintendent of the Garden at the John Innes Horticultural Institute, Merton, Surrey, in succession to the late Mr. E. J. ALLARD. Mr. HOSKINS is a Cumbrian, who commenced his gardening career in the gardens at Penalverne, Penzance, the residence of T. R. BOLITHO, Esq., where he was employed for five years. Fifteen months of training at Kew followed, and from Kew he went to the Cambridge University Botanic Gardens, where he remained senior foreman for eleven years. From Cambridge Mr. HOSKINS obtained the position of lecturer and head of the horticultural department under the Lancashire County Council, and was at the same time Hon. Lecturer on Plant Pathology at Liverpool University. After three years' work in the Lancashire district he was appointed lecturer and superintendent of the Horticultural Department at the West of Scotland Agricultural College, here with a district covering no fewer than ten counties. Mr. HOSKINS conducted classes for teachers in school gardening, and many keen Lads formed a demonstration fruit plot and demonstration school garden plots at Kilmarnock, had charge of the gardens at Auchincruive House, and supervised the establishment of a Fruit Demonstration Farm at Lugar, besides lecturing and advising throughout a district covering the active

MR. A. HOSKINS, THE NEW SUPERINTENDENT OF THE JOHN INNES HORTICULTURAL INSTITUTE.

Garden of the College. As an author Mr. HOSKINS is best known by his book, *Soil: A Gardeners, with an Appendix on Fertilizers*. He has also written Extension Leaflets, and Bulletins on Soil, Gardening, etc., issued by the West of Scotland Agricultural College. The late Mr. ALLARD Mr. HOSKINS has taken the keenest interest in his work, and won the high esteem of all his associates as a practical demonstrator and capable lecturer. His wide experience in many ways as a specialist and thorough cultivator fits him for his post at Merton, and Kewites will be delighted to know that the important post of Superintendent at the John Innes Horticultural Institute is to be held for a second time by a former member of the Kew Garden staff.

A New Botanical Journal. The first number of the new American journal, *Botanical Abstracts*, has just reached this country. Published in September, 1918, it appears rather later than had been at first expected. On the front page the Editorial Board is given as follows: Editorial Board: BURTON E. LIVINGSTON, Editor in Chief, The Johns Hopkins University, Baltimore, Maryland; J. H. BARNHART, New York Botanical Garden, New York City, Editor for Bibliography, Biography, and History; E. W. BERRY, The Johns Hopkins University, Baltimore, Md., Editor for Paleobotany and Evolutionary History; C. J. CHAMBERLAIN, The University of Chicago, Chicago, Ill., Editor of Cytology; W. H. CHANDLER, Cornell University, Ithaca, N.Y., Editor for Horticulture; H. J. CONN, New York Agricultural Experiment Station, Geneva, N.Y., Editor for Bacteriology; H. C. COWLES, The University of Chicago, Chicago, Ill., Editor for Ecology and Plant Geography; B. M. DUGGAR, Missouri Botanical Garden, St. Louis, Mo., Editor for Physiology; C. STUART GAGER, Brooklyn Botanic Garden, Brooklyn, N.Y., Editor for Botanical Education; G. M. GREENMAN, Missouri Botanical Garden, St. Louis, Mo., Editor for Taxonomy of Seed-Plants and Vascular Cryptograms; HENRY KRAEMER, University of Michigan, Ann Arbor, Mich., Editor for Pharmacognosy; DONALD REDDICK, Cornell University, Ithaca, N.Y., Editor for Pathology; J. R. SCHRAMM, Cornell University, Ithaca, N.Y., Editor for Taxonomy of Non-Vascular Cryptograms; G. H. SHULL, Princeton University, Princeton, N.J., Editor for Genetics; E. W. SINNOTT, Connecticut Agricultural College, Storrs, Conn., Editor for Morphology, Anatomy, and Histology; RAPHAEL ZON, U.S. Forest Service, Washington, D.C., Editor for Forestry. The Editors for Agronomy, Soil Technology, and Plant Production will be announced later, as also will the sectional editors for other countries than the United States. The journal is published as an Allied protest against the German published *Botanisches Centralblatt*. The work is intended to be international, and to give rapid publication of abstracts of all papers bearing on botanical science published in all parts of the world. Editors for each subject are being arranged in Allied countries. The first number consists of 36 pages, 7 inches by 10½ inches. It would make it much easier for readers to find the subjects in which they were particularly interested if, on the cover, the page number on which abstracts under that heading appeared were given. A change which would be much more difficult to make, and which perhaps would have to be deferred until the first volume is complete, is the change in the width of the printing column in the page. As it is, the printing column is 5 inches wide, while the average international card index card is about one-eighth inch less, and in any case a margin is necessary, so that a printing column of 4½ inches would be more useful for those who wish to cut up and paste each reference on a card index. In other respects, the editors can be warmly congratulated on a well printed, clearly spaced, serviceable journal, which should be in the hands of all botanists.

The Anatomy of the Potato Plant. This excellent and beautifully illustrated description of the anatomy of the Potato plant[*] should be studied by all engaged in scientific investigation of the Potato, and in particular by plant pathologists. From the practical point of view it contains much that is of interest. The observations on the distribution and frequent anastomoses of the phloem elements (sieve tubes), including the development of secondary phloem at the time of flowering are evidently correlated with the need for large tracts of crude sap-conducting tissues in order to admit of the amassing of starch by the tuber. The author also shows that the view often put forward that the bulk of the tuber is formed by the pith is inaccurate, and that it is the cellular tissue external to the pith which contributes most to the body of the tuber.

The Storage of Sulphate of Ammonia.—In the Food Production Leaflet No. 53, issued by the Board of Agriculture, it is pointed out that whether sulphate of ammonia is stored in bags or loose in a heap, the building in which it is kept should be dry and an efficient protection from rain. Sacks of sulphate of ammonia

* Philippe de Vilmorin, Report of the International Botanical Congress, 1910.

* "Anatomy of the Potato Plant, with Special Reference to the Ontogeny of the Vascular System," by E. F. Artschwager, *Journ. of Agric. Research*, Washington, XIV., No. 6.

should be piled on a platform raised 6 inches from the floor, a 3 inch layer of some dry substance being placed beneath the platform to absorb any moisture draining from the sacks. The dry substance may be either Castor-meal, Rape-meal, bone-flour, or raw-bone meal (which can be afterwards used as fertilisers), but chalk, lime, or basic slag must not be used, as they would liberate ammonia from the sulphate. When the sulphate of ammonia is to be stored in a heap, the floor should first be covered to a depth of 6 inches with one of the absorbent substances mentioned above (failing these, a layer of dry soil, sand, or sawdust may be used.) Before being applied to the land the sulphate should be freed from lumps, and may with advantage be passed through a ¼ inch riddle. This will not be necessary in the case of "neutral" sulphate (i.e. containing less than 0.025 per cent. of free acid), which contains no lumps and does not cake. Farmers are recommended to secure the neutral sulphate wherever possible, as this does not rot the bags, and can, moreover, be applied to the land through a drill.

War Items.—We learn with regret that Corpl. EDWARD HERBERT FISHENDEN, 7th Batt. Royal West Kents, has died of wounds received in action on November 5, in France. He was the only remaining and youngest son of Mr. and Mrs. E. H. FISHENDEN, of The Gardens, Great Culverden, Tunbridge Wells. He was only 19½ years of age, and joined the Colours in October, 1914. He had two years' service in France, had been wounded three times, and gassed once. In August, 1917, he was made King's Corporal on the field for gallantry. He passed peacefully away on November 7, and is laid to rest in the British Military Cemetery at Premont. Mr. and Mrs. FISHENDEN lost their eldest son, Signalman H. A. FISHENDEN, aged 31 years, in January of this year. He went down with his ship, H.M.S. "Racoon." Their daughter is serving with Q.M.A.A.C. Corpl. FISHENDEN started work in the gardens at Woodbridge Abbey, Suffolk, where his father was gardener. He went to Tunbridge Wells about five years ago, where he was employed with his father at The Huntleys. Signalman HARRY A. FISHENDEN commenced his gardening career under his father at Stutton Hall, near Ipswich. He was later employed at the Chantry Gardens, Ipswich; at Shorcham Place, Kent; East Sutton Park; Park Hatch, Surrey; and Belton Gardens, Isle of Man. His last position was as gardener to Mrs. BLACK, Cranham Holme, Upminster. He joined the Navy on the outbreak of war.

—— M. MAURICE MADELIN, for some time employed by Messrs. W. WELLS AND CO., of Merstham, has been employed as interpreter with an American infantry regiment. His many friends in this country will be interested to know that he has been awarded the Croix de Guerre.

—— M. PINGUET-GUINDON, of Tours, has had the great misfortune to lose both his sons in the war. The younger, LOUIS, was killed before his brother ROGER, a sergeant major in the Engineers, who died from wounds received at Villotte only a short time before the armistice was signed.

—— We regret to learn that Lieut. ROBERT CROUX, son of the well-known fruit-tree grower, M. CROUX, of Chatenay (Seine), was mortally wounded in action quite recently.

(Published by U.S. Department of Agriculture as Bulletin No. 712.)

THE MARKET FRUIT GARDEN.

NOVEMBER is commonly considered to be the best month for planting fruit trees, but it is seldom that it offers such favourable opportunities for the work as it did this year. It is true that the rainfall at my place was about normal, 2.40 inches falling on thirteen days, but there was a period of twelve days without rain from the 12th to the 23rd inclusive—indeed, there was little to interrupt the work from the former date to the end of the month. Twelve white frosts were recorded, the thermometer on the grass registering 7° on two occasions, but the frost was never of sufficient duration to harden the ground and make the soil unworkable. Thus the trees have gone in very well indeed. Good progress has also been made with the digging of the older plantations, work which must still be done by women, owing to the scarcity of male labour. The women have now learned to dig fairly well, though they are slow, owing to the work being really beyond their strength. The fixed wage for women is now 5d. per hour, and at this rate the operation is very expensive. I cannot, however, see any satisfactory way of escaping it where the trees and bushes have grown to such an extent as to prevent horse cultivation. Where this is not the case I am going to try the new Fruit Farm plough invented by Messrs. Seabrook and Udall, a description of which was given in *Gard. Chron.*, Sept. 7, 1918, page 103. The implement has arrived, but has not yet been tested. Should its work fulfil expectations it will effect considerable economy in the cultivation of market plantations.

YOUNG FRUIT TREES.

There appear to be only two ways of obtaining exactly the kind of young fruit trees suitable for planting. The best is, no doubt, to see them growing in the nursery. The other is to buy maidens and train them yourself. Even then the buyer is quite in the nurseryman's hands with regard to the stock on which they are worked. As mentioned in a previous article, I required bushes on the Paradise with 18-inch stems. It was necessary to go to five nurserymen to get these in the varieties selected, and then few of them could guarantee quite this length of stem. No doubt they have done their best, but few of the trees have stems much over 12 inches to 15 inches long. However, most of them have something of a stem, so that it is possible to put a narrow band of wire netting round them to prevent gnawing by rabbits. The question is, how wide a band is necessary to ensure safety? We have previously used 2 feet bands for half-standards. I think 1½ foot is sufficient, but am doubtful whether less will prove an absolute protection. Of course, the rabbits could stand up and gnaw the lower branches, but it is hoped that a fairly wide circle of netting, standing well away from the stem, will alarm them even if it does not render their mischief a physical impossibility. The first spell of severe weather will probably settle the point. At any rate, the stems will be safe, and that is the vital point.

BROWN ROT ON PLUM TREES.

It would be difficult to imagine anything more tedious in the way of pruning than the treatment of large Plum trees that have been severely attacked by brown rot. This disease was very prevalent at blooming time last spring, particularly on the variety Czar. Most of the brown leaves were then pulled off, but there are hundreds of dead spurs showing plainly now that the leaves have fallen. There is no doubt that these should be removed, because they contain the winter resting stage of the fungus, which is capable of developing next spring, and, in favourable conditions, distributing spores to germinate on healthy leaves. It is a safe rule that dead and diseased wood of all descriptions should be removed in the winter pruning of all fruit trees. Unless this is done it is doubtful whether spraying can be completely successful. At any rate, one process helps the other. Large pieces of wood should be collected and burnt, but it is impossible to gather up small bits, such as spurs, in a large plantation. The next best treatment is to dig them into the ground. Even if they have to be left on the surface, they are less liable to do harm there than on the trees.

WINTER MOTH.

The wingless females of the Winter Moth began to ascend the trees in large numbers about the middle of November, as shown by those trapped on the grease-bands. The catch of males is even more numerous, many of the bands being thickly sprinkled with them. This is, perhaps, rather a drawback than otherwise, as there is little to be gained by destroying males, whilst their bodies reduce the sticky area of the bands and may enable females to pass over in some cases. The fact of there being so many moths shows that plenty of caterpillars survived spraying with arsenate of lead in the spring, and were able to complete their life-cycle.

SPRAYING MACHINES.

For several years spraying has been done here with a "battery" of pneumatic knapsack sprayers, charged with both air and liquid from one powerful pump. The system has worked well enough, but the apparatus was practically worn out at the close of last spraying season. In selecting a new machine I aimed at something that would get over the ground more rapidly and deliver the spray with more pressure behind it. The latter is an important point when the trees grow tall, and it is also very desirable when dealing with aphides. After careful consideration it has been decided that nothing less than a power sprayer, driven by a petrol-paraffin engine, would prove really satisfactory in orchards arranged as they are here.

In selecting spraying apparatus there are several points to be taken into account. In orchards with plenty of space between the trees, and no bushes or other crops beneath them, one of the numerous manual sprayers, with tank and pump on wheels, moved in much the same way as a wheelbarrow, does good work. On hilly or soft ground, however, it is almost impossible to shift such an outfit. A horse-drawn machine with manual pump overcomes this difficulty, but has the disadvantage of keeping a horse standing where it might be doing more useful work elsewhere. For orchards where it is impossible to draw a machine between the rows the choice is between knapsack sprayers and outfits which have the pump and tank on the headland and deliver the fluid through long hoses. Knapsack sprayers answer very well indeed if the trees are reasonably small, and there is nothing more convenient for getting about amongst crowded growth, but they are too slow on a large place, and have insufficient power for tall trees. Of machines to work from the headland there are two classes, manual and power. Some of the former are pumped by one man, others by two, but my experience is that all powerful pumps need two men to obtain sufficient force behind the spray. Catalogues too often state that such outfits "will easily supply up to 8 nozzles at a distance of 200 to 300 yards," but the makers hesitate to corroborate such statements if approached personally. There is no doubt that these machines entail very hard work and use a lot of labour. There remain, then, the power sprayers, several excellent types of which are on the market. The outfit I have selected delivers the fluid through a portable steel main, made in 15-feet lengths, with three-way cocks at intervals, to which rubber hoses can be attached, leading to the lances and nozzles. The main is laid down between the rows, and a large area can be

sprayed on each side of the main if 60 feet rubber hoses are used. A horse is necessary to draw the machine from one field to another, but it would not be difficult to move it along the headland by hand. With such an outfit it will be possible to get over the ground rapidly, a point of vital importance in dealing with serious attacks by insect pests, such as the caterpillar infestations of recent years. I imagine that it may take about half an hour to shift the main, but, once that is done, spraying will go on continuously.—*Market Grower.*

CULTURAL MEMORANDA.

PRUNING NEWLY-PLANTED APPLE TREES.

I was very interested in the note on p. 220 by *E. M.* on the subject of pruning newly planted Apple trees, and cordially agree with him that it is a very bad practice to leave young fruit trees unpruned the season they are planted.

In my opinion, this, and one other common mistake, is answerable for the many miserable and stunted orchard trees one sees in all parts of the country, and unless remedial measures are taken in good time such trees will never make healthy and productive specimens.

The majority of amateurs are afraid to prune for fear of doing harm, and I believe that advice is often given them not to prune newly-planted fruit trees. If young trees are normal, healthy specimens, they should always be moderately pruned the same season, perhaps rather later than one usually prunes. I usually do it just before growth commences in the spring. Many people are more concerned about the few fruits they obtain the first season than about building up a strong tree for the future, and yet in the case of other fruits, such as the vine, they would condemn the practice.

The second common error is that of allowing the grass to grow close up to the stems of young fruit trees. I believe that two operations in orchard Apple culture, viz., pruning the first season and keeping the ground clean, are the principal steps towards success.

When visiting the R.H.S. Gardens at Wisley last year, I saw in the experimental quarter a striking confirmation of the evil results of letting the grass grow close to the stems of fruit trees. Various experiments had been made, but so pronounced were the disastrous results of leaving the grass to grow around the stems that no one seeing them could but be convinced of the evil's of the practice.

When asked to advise on the subject of planting fruit trees in grass, I always suggest stations 6 feet in diameter, the stations to be kept quite clear of grass and weeds, and increased in size as the trees grow. In cases where trees have become stunted, by over cropping in a young state, non-pruning when newly planted, allowing the grass to grow over their roots, or by a combination of these evils, I would suggest hard pruning as the only treatment likely to be permanently successful, allowing the trees to carry very little fruit for a year, clearing the soil for several feet around the base of the tree, and giving mannrial assistance.

I have had a striking illustration of what this treatment can produce. Many years ago, after planting some standard orchard trees, one or two trees of Lane's Prince Albert became stunted and persistently refused to grow, and bore a quantity of small fruits. I cut the stunted growth off almost close to the head of the standard, with the result that a new head of clean growths was made the first season afterwards, thus laying the foundation of a healthy and vigorous tree.—*J. G. Weston, Eastwell Park Gardens.*

FRUIT REGISTER.

PEAR PASSE CRASSANE.

RAISED by M. Boisbunel, of Rouen, and first fruited in 1855, the Pear named Passe Crassane syn. Passe Crasanne) has come to be regarded as one of the best of varieties for use at Christmas time, notwithstanding the late Mr. Blackmore's contention that it was worthless at Teddington. It is fortunate for those who have a fair crop of this excellent Pear this season that the fruits do not all ripen at the same time; indeed, many specimens will be in first-rate condition in February and March, if kept in a proper fruit room, even though the majority may be served for dessert during the Christmas and New Year season. The medium sized, roundish obovate fruits are dark, russety brown, with slight yellow shading. The flesh is melting, rich and aromatic. Mr. Geo. Woodward regards Passe Crassane as a Christmas Doyenne du Comice, and considers high cultivation necessary to bring the fruits to perfection. Some years ago, at Barham Court, he grew specimens weighing upwards of 14 ounces.—*B.*

LETTERS FROM SOLDIER-GARDENERS.

BULGARIA.

POSSIBLY a few brief notes from an erstwhile gardener now on service in Bulgaria may be of interest to those readers who have not had the fortune, or, as we are often inclined to think it, the misfortune, to visit the Balkan States; on one or two previous occasions I have sent notes from Macedonia, but they would be incomplete without one from the country we have so recently conquered and travelled through.

South of the Belashitza Mountains, which divide Bulgaria from Greece, or Macedonia

to spot the county, while topographically somewhat similar, is in reality entirely different from that on the northern side; the climate of Greece is much drier, and the soil itself of a sandier and more calcareous nature, much more arid and barren, while in Bulgaria and Serbia the atmosphere seems much more damp and humid, and the soil is vastly more fertile, being much stronger and dark in colour, in many places almost resembling old potting soil, or a mixture of loam and leaf mould.

Naturally, field and garden crops flourish here with little or no artificial assistance, and if only the natives would appreciate the vast possibilities of their country from an agricultural and horticultural point of view, there would certainly be far less poverty among them.

At present, however, every peasant appears to be a small holder on a limited scale, and on his small patch of land he and his family are almost wholly dependent for their food supply. The staple food crop is Maize, which grows to perfection; the Corn cobs are harvested by hand picking by the women and children. After being dried and stripped of their outer covering, the Corn is ground by the old-fashioned stone-milling process, and the flour, or meal, used for all baking purposes, while the offal is the only form of grain food used for oxen, which do all transport work both on the land and by road. The Maize straw is used for a variety of purposes, but principally as winter fodder for cattle.

Vegetables are grown in small quantities, but always of excellent quality; the most important is a large and somewhat coarse variety of Vegetable Marrow, which is sown in the open fields between the rows of Maize. The Marrows are never cut green, but are left on the plants to ripen until the maize is harvested, when they are collected and stored for winter use.

I might add, in passing, that these ripe Marrows, far from being tough, are most excellent when cooked, the writer having, in less peaceful days, on more than one occasion assisted in rescuing these vegetables from our late enemy's abandoned stores, and a most welcome addition they made to our Army rations.

Cabbage, of a variety not unlike a small Ox Cabbage, is grown in small quantities, as also are Leeks, but these latter are almost invariably used before they come to maturity.

Aubergines are a favourite crop, but their fruit is seldom cooked to the best advantage, and a large variety of Capsicum is also widely grown, every cottage and hut having strings of the brightly-coloured pods hung out to dry during the autumn.

The most favoured garden crop, however, is the Tomato; the seeds are sown in the open ground, and without the least attention the plants produce amazing crops of fruit. The plants are allowed to branch and straggle along the ground in tangled profusion, but they always appear to bear a wonderful quantity of fruit of remarkable quality.

For flowers or decorative plants the Slav races appear to have no use or liking at all, but my notes would be incomplete without mention of Tobacco, which, next to Maize, is by far the most important and, I should judge, the most lucrative product of the land. I have been unable, so far, to name the variety, but the plants, which reach a height of upwards of 6 feet, bear broad leaves of very fine texture, surmounted by a small, deep pink inflorescence. Of the finished product I am afraid that I personally cannot speak in terms of very great admiration, as the scent and flavour leave much to be desired, but I believe it is regarded by the natives and some connoisseurs as being of excellent quality; certainly it is far preferable to the tobacco smoked by the German troops, which is not unlike chips of Oak bark.

Cotton is grown here in some districts, but I have never seen anything in the nature of a Cotton mill or factory, so am unable to say what use is made of it.

Huge tracts of fertile land between the many mountain ranges and spurs are at present uncultivated, though this may, of course, be due to the war time conditions which have so long prevailed, but the fact remains that from a food producing standpoint this country should rank second to none in the Balkan States. *J. E. Palmer (78th Field Ambulance), late of Felstone Gardens, Tarporley, Cheshire.*

THE ONION FLY.

THE Onion fly is rather smaller than the ordinary house fly, which it very much resembles. It hatches about the first week in May from a chrysalis which has remained in the ground all the winter, and commences laying its eggs on the Onion plants about a week later. The eggs require a little moisture to assist hatching, consequently when deposited during dry weather they remain dormant until the first wet day, when they quickly hatch and the grubs begin to eat their way into the tiny bulb. The fly cannot survive frost, and if frost or very cold weather occurs just after the grubs are hatched many are destroyed before they have time to do any damage. This is the reason why the pest is not so troublesome in some seasons as in others. The fly is guided to the Onion by its sense of smell, and an unhealthy plant or one that has been attacked by wire-worm or other ground insect always seems to be the first attacked. It is by obliterating the smell of the Onion that such things as soot or paraffin are use-

FIG. 96.—THE ONION FLY: ANTHOMYIA CEPARUM. (Maggot and Pupa, magnified.)

ful. After the grubs are fully grown, which takes two or three weeks, they leave the Onion and bury themselves in the ground at a depth varying according to the condition of the soil, but seldom more than 6 inches. Before the grubs leave the Onion they may be killed by paraffin emulsion at a strength of one in ten; this specific will not harm the Onions, but will kill the grub if it reaches them in less than an hour. In preparing soil for an Onion bed it is a good plan to trench it two spits deep and very carefully bury the top spit, in which most of the chrysalids harbour, for as the fly emerges directly from the chrysalis it cannot emerge through, say, 12 inches of soil, and so it perishes. Directly the first flies make their appearance efforts should be made to poison them. Their ordinary food is pollen and decaying vegetable refuse, but they are very fond of anything sweet, and can be easily poisoned by placing ordinary fly papers soaked in sweetened water in saucers between the rows of Onions during fine weather. They can also be caught on ordinary sticky fly papers stretched between the rows. By poisoning or catching the first few flies, more can be done to prevent the ravages of the grubs than all the deterrents put together. Without doubt the best way for anyone who cannot succeed is to refrain from growing Onions for one year, as the pest would then die out, and although flies do migrate to some extent, there would be insufficient to destroy a crop grown, say, one hundred yards from where they were grown the previous year. These methods can also be applied to the Carrot fly and the Cabbage root maggot fly with equal success. *W. Robinson, Sunny Bank, Eaton, Gaisland, Lancashire.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Chamber of Horticulture.—It is to be hoped that growers joining the Chamber will, in their own interests, make it the early business of a committee to inquire into, and press for legislation relating to, a minimum standard quality for commercial chemical sprays bearing well-known names such as lime sulphur, arsenate of lead, potassium sulphide (liver of sulphur), and others. We advocated such legislation in the Press some years ago, and are now more strongly than ever convinced of its necessity if growers are to be safeguarded. The question of commercial copper sprays for fungous diseases is on another plane, as the percentage of copper gives no real clue to their effectiveness, for reasons well known to scientists and proved by the practical experience of growers. It is also evident that materials such as are offered by reputable firms made to their own research formulae (and not coming under general classification and nomenclature such as the examples given) could not fairly be controlled. *Walter Voss and Co., Ltd.*

Bud Variation in Potatos.—I am glad that Mr. Taylor, on p. 229, calls attention to a statement in my Ormskirk paper, which I admit gives ground for criticism, and requires explanation. It would have been more accurate to state that "in nearly every instance" where a new variety is said to have arisen by bud variation, the whole of the tubers at the base of the plant, when lifted, differ entirely from others in the plot. The present discussion, I think, began by one of your correspondents advising Potato growers not to remove so-call'ed "rogues" from their Potato crops, as they might prove to be new and distinct varieties of superior merit, and it is beyond all question that the plants so referred to would, when lifted, be found to be bearing tubers which were all like one another, and different from the rest of the tubers in the crop. That there are cases where one or more tubers at the base of a plant differ in certain respects from the others, is a fact with which we are all familiar, but no one has ever suggested that the presence of such tubers would so alter the character of the plant as to give it the appearance of a "rogue" in the growing crop, the presence of such tuber or tubers being only noticeable when the crop was lifted. It would have helped us all if Mr. Taylor had explained precisely what he meant by the term "mutants," for the first essential, in considering a subject like the present, is to be exact in regard to the terms used. Presumably Mr. Taylor implies by the term "mutant" a new and distinct variety, and not merely a colour variation. But although Mr. Taylor reports that he has obtained two instances this year where certain tubers differ from others borne upon the same plant, neither he nor anyone else has given a single instance of any one of the distinct varieties of Potatos now in commerce having arisen in this way. There is no reason to suppose that in the two "mutants" Mr. Taylor has obtained this year, we shall find that nature has adopted an abnormal method of originating new and distinct varieties, and we may anticipate that these "mutants" will, under cultivation, if they differ in any way from the type, do so only in regard to the colour of the skin. In your issue of November 23, Mr. Jackson made some further quotations from Darwin in support of the claim that new and distinct varieties of Potatos have arisen by bud-variation as well as from grafts. It is obvious, however, from a study of the context, that Darwin was quoting the reports of experiments made by others rather than by himself. There is nothing to show that Darwin had any opportunity of testing the accuracy of the statements made to him, or saw the "sports" to which they referred. I see no reason, therefore, why we should take the views expressed by Darwin as final or authoritative, more especially if these are at variance with the experience of practical and scientific Potato growers of to-day, who are at least as careful and experienced as those upon whom Darwin was obliged to rely. If new and distinct varieties arose in the manner stated, we should expect the same results to-day, but, as mentioned above, no one is able to point to any one of the Potatos now in cultivation as having originated either by bud

variation, or from grafts. The reports given of the varied forms obtained by grafting Potatos are at first sight remarkable, but as the grafts were taken from many very different varieties, one would naturally expect the same diversity in the plants and tubers which they produced. Mr. Jackson mentions that he still has a number of tubers of one of his "sports" ready to sprout for next year's planting, and if he can send some to Ormskirk next year it would be interesting to see how far they can be identified with existing varieties. I fully appreciate the friendly tone of Mr. Jackson's letter, and agree with him that so-called "sports" should be submitted to the most rigorous tests. *Arthur W. Sutton.*

Government Housing Scheme. My committee feels that it is advisable when considering the housing scheme, sufficient ground should be allotted to each house to enable the occupier not only to grow sufficient vegetables for his family's consumption, but fruit also. This would mean four to six houses per acre. Land adjoining the house is much preferable to separate allotment ground, as ensuring economy of the worker's time. To ensure consideration being given to the above, it suggests that a representative of horticultural sub-committees be appointed on any county or local committee formed under the housing scheme. *T. H. Sayers, Organising Secretary, Horticultural Sub Committee for East Kent, Kent War Agricultural Committee.*

The Pagoda at Kew. The illustration in fig. 90 of the Pagoda at Kew reminds me of a story I heard from Sir J. D. Hooker. When first built it was provided with brass bells hanging from the projecting roofs. They suddenly disappeared. It was discovered that George IV. sold them to pay his debts! *Geo. Hyslop, Dunchurst, Bankcome Wood Road, Bournemouth.*

Silver Leaf Disease.—I believe it would help those who are endeavouring to combat Silver Leaf disease if owners of affected Peach and Plum orchards would state the age of their trees, and the nature of the subsoil. In all cases of Silver Leaf that have come under my observation, diseased trees, whether Peaches or Plums, have been aged ones with strong, deep roots growing in stiff, clay soil. This seems to suggest that the fungus causing Silver Leaf (Stereum purpureum) follows as the result of the roots of the trees entering an unsuitable clay subsoil. If this theory be correct, we can in future prevent the spread of Silver Leaf by root pruning and lifting the fruit trees. *John Bates, Mentmil Gardens, Stow.*

Mr. E. Molyneux's thoughtful queries on p. 240 concerning Silver Leaf disease are certainly deserving of the fullest attention from all interested in fruit growing. As Mr. Molyneux suggests, the cutting out of affected branches or the destruction of affected trees is no real remedy. That the Food Production Department of the Board of Agriculture cannot at present fully enlighten us upon this insidious disease is doubtless due to the fact that much research work remains to be done before a remedy or a deterrent to the disease is found which will enable Silver Leaf to be thoroughly stamped out in the orchards and gardens of Great Britain. Without claiming to any scientific knowledge upon the matter, and lacking the opportunity of laboratory tests and inner research work, I am of the opinion that the disease is essentially a soil organism, and any attacks made upon a tree must first come from "under" or "at" ground level. If ultimately this view should prove incorrect, then I should fall back upon the belief that bad conditions of soil and drainage, or direct injury to the trees, are the main causes of the complaint. The reason I suggested that grafted trees seemed more subject to disease than trees upon their own roots was due to my own observations, and to the fact that an imperfect graft union would provide an easy means for spores of the disease to enter the tree. Further, having observed many Plums, Cherries, etc., upon their own roots in farm and cottage gardens, I have not known of a single instance of Silver Leaf occurring among such trees. Though I recognise the truth of Mr. Molyneux's assertion that the majority of modern fruit trees are necessarily "grafted" trees, the fact remains that many old world trees were perpetuated by suckers, or originated as seedlings among cottage folk. Amongst Plums the variety Victoria seems the most susceptible to the complaint, and for this reason for the past few seasons I have omitted this Plum from my list of desirable varieties for new fruit plantations. I do not know what Mr. Molyneux's experiences are, but it seems to me that the majority of trees which suffer from Silver Leaf do not show the disease until the roots have grown well down into the subsoil. This seems to be an especially noticeable feature with trees in heavy soil. The reason for the upper branches often dying first seems to be due solely to the fact that the upward flow of sap slackens as the disease gains headway. Very noteworthy, too, is the rapid decay of the heartwood, which also points to the view that the attack is not an external one, upon the foliage. Were the attack in this simple form it could doubtless be kept in check by spraying. I would advise that all heavy soil should be broken up thoroughly before planting fruit trees, the incorporation of lime rubble (or mortar rubble) and charcoal in good quantities, the selection of varieties that appear to be immune, and very special care after planting in the use of the spade in fruit plantations. Any facts that can be brought to light regarding soils which are (or are not) subject to the spread of the disease, varieties that are subject, and varieties that are immune, and any suggestions as to a remedy, or, better still, a preventive, would prove invaluable. I would further suggest that planters of Plums and Cherries should examine the trees and record any that carry serious abrasions low down on the bark or any with imperfectly healed graft unions. *P. S. Hayward.*

The Fruiting of Cupressus funebris see p. 232).—We have often found cones on Cupressus funebris, but never on trees under 10 to 15 years old, and the coning specimens are always pot bound. All our present stock has been raised from home-saved seeds, although I consider cuttings the quickest method of raising plants. *G. H. S., Abbeyon Hall Gardens, Loughy Mill, Derbyshire.*

Peat versus Leaf-mould. In the course of his interesting "Notes from Kew," Mr. Watson remarks (p. 223) that leaf mould should be sterilised to avoid the risk of bringing eel worms into the garden. I have long been convinced of the superiority of peat as plant food and fertiliser, inasmuch as, before it is applied to the soil, it neither harbours eel worms, slugs, snails, or other animal pests, nor permits fungous growth of any kind. Its antiseptic properties, however, do not render it indigestible by plants, for one may see how readily seedlings send their rootlets into particles of peat and thrive on it. Peat, of course, is not found in every district; but, where it does exist, is it always naturally in a fit state for use. The wet, acid stuff out of a peat moss could not be applied to land immediately without detriment to the crop, but exposure to sun and frost soon disintegrates it and deprives it of acidity. Where peat is cut for fuel, there is always plenty of dry, pulverised material lying about, which, when riddled, makes a beautiful compost. Best of all is the accumulated dust "peat stour," as we call it, beneath an established peat stack. *Herbert Maxwell, Monreith.*

SOCIETIES.

DUMFRIES AND DISTRICT HORTICULTURAL.

NOVEMBER 30.—The annual meeting of the Dumfries and District Horticultural Society was held in the Wesley Hall, Dumfries, on the 30th ult. In the absence of the president, through illness, Mr. A. W. M'Alister, vice-president, presided. The following office bearers were appointed: President, Provost S. Arnott, Sunnymead, Maxwelltown; vice-presidents, Mr. A. W. M'Alister, Mr. J. L. Armstrong, Mr. J. Croall, Mr. J. Maxwell Gray and Mr. W. Hutchinson; secretary and treasurer, Mr. T. Douglas, Greenbrae, Dumfries; members of committee, Mr. Brown, Portrack, and Mr. M'Leod, Dalawoodie (gardeners), Mr. Carson and Mr. Thos. Hunter (traders), and Mr. R. M'Gill and Mr. O. Robertson (amateurs).

CROPS AND STOCK ON THE HOME FARM.

CHALKING LAND.

FROM the presence of so many large pits and quarries in chalk districts we must assume our forefathers employed chalk largely in their agricultural operations. Chalk is practically pure calcium carbonate, and its application to land during the winter, at the rate of 20 tons per acre, provides useful work for horses and men at a time when the land is frostbound. The chalk should be spread evenly over the surface where it may be pulverised by frost, rain and wind, and thus gradually mix with the soil, setting free some of the humus therein, but not to the extent that lime does. Chalk ameliorates the physical character of the soil, rendering stiff soil more easy to manipulate, and is especially useful in fields where Turnips and Swedes are badly affected with Finger and Toe disease.

EMPTYING THE MANURE YARDS.

The present is a good time to clean out the manure yards ready for the reception of cattle for the winter. Where manure is not required for the Wheat crop it should be carted on to land intended for Mangold, Cabbage, and Potatos next season, tipped out in heaps, and spread evenly over the ground subsequently. Manure applied to the land at this season for the crops noted provides food by the time the crops are in a position to assimilate it.

Some of the yards may require repairing at the base; holes should be filled with chalk or stones to render them as dry as possible, and allow a slope to carry away water from heavy rains, thus adding to the comfort and welfare of the cattle. Every yard should have a shed attached wherein the cattle can shelter during wet or cold, windy weather by day or night.

WINTER FALLOWS.

The land intended for spring sown Oats, Barley, Mangold, Turnips, Swedes, Vetches and Maize should now be ploughed—winter fallowed. Generally these crops follow cereals and provide a distinct change that is beneficial to the future crop.

If it so happens that the previous straw crop was cut high owing to bad corn, or an ample supply of stubble was left on heavy land, the straw is valuable in assisting the future working of the soil as the stubble decomposes.

The ploughing of such stubbles affords useful work for the horses when the ordinary fallow land cannot be worked without doing much harm to spring cultivation.

THE PLOUGHING OF GRASS LAND.

The enforced provision of more arable land by the ploughing up of permanent pasture is likely to take place for the spring sowing of cereal crops.

Many persons who are required to plough pasture land and who have no previous experience will wonder when is the best time to plough to obtain the best results, as there are so many opinions, naturally, on such a wide subject.

Where Oats or Barley are to be grown my experience and observation leads me to state that the month of February or early in March is the most likely period for the crops to escape the ravages of wireworm, which is a foe to guard against.

When ploughing is done in the autumn the turf has mainly decayed by sowing time in March, and the wireworm is by that time waiting for the cereal growth, and thus much injury is done to the Oat or Barley crop.

No amount of rolling or the sowing of strong stimulants, such as nitrate of soda or sulphate of ammonia, will check the destruction of the corn crop when once it is attacked by wireworm; accelerate the growth before an attack if you like, but not after.

Where Potatos are to follow the grass crop plough as early as possible, thoroughly burying the grass by the aid of the skim coulter. If once ploughing is done early in February the turf will be readily decomposed, and the ploughing will expose many of the wireworms to the attack by birds, thus cleansing the land to a large extent and providing a good tilth for future cultivation. *E. Molyneux.*

SERBIA AND ENGLISH FARMERS' GIFTS.

The Serbian Government are placing at the disposal of the Agricultural Relief of Allies Committee one of the largest national farm depots in Serbia for the reception and maintenance, pending distribution, of the British live stock which the Committee hope shortly to send out as a gift from farmers in this country. The stock, it is hoped, will in some measure assist the peasants to resume cultivation of the lands to which they are now returning, and the Committee welcomes the help of farmers to make the gift as useful and substantial as possible.

TRADE NOTES.

NEW PRICES FOR APPLES.

OWING to the removal of restrictions on the importation of Apples the Food Controller has issued an Order, which comes into force on the 16th inst., revoking as from that date the Apples and Perry Pears (Sales) Order, 1918. The new Order controls the price of all Apples, whether home grown or imported.

The maximum retail price is 9d per lb., and retailers are required to exhibit notices stating this price. The maximum price on sale by the first owner (i.e., the importer or grower) is as follows:—

HOME-GROWN APPLES.

First owner's price, 58s. 4d per cwt. (packages may be charged for as provided by the Order).

IMPORTED APPLES.

When sold in packages.	At the rate of per barrel s. d.
Nova Scotian, sold in a barrel containing not less than 112lb.	58 4
Canadian, Maine, ditto, ditto, 130lb.	67 8
Virginian and Western States, ditto	67 8
	per case.
British Columbian, sold in a case containing not less than 38lb.	19 9
Washington, ditto, ditto, 38lb.	19 9
Californian, ditto, 38lb.	19 9
Oregon, ditto, 38lb.	19 9
	per cwt.
Any variety of imported Apples, sold otherwise than in the packages mentioned above	56 0

NOTE.—No additional charge may be made for any package.

The prices to the importer fixed for imported Apples are based on the existing freight rates of £1 per barrel and 5s. per case, together with 5 per cent. for primage. These prices may from time to time be modified to meet variation in these charges, or other variations in cost.

On a wholesale sale of any Apples by a person other than the first owner the maximum price is the first owner's price, together with the addition of 6s. per scheduled barrel, or 2s. per scheduled case, or 10 per cent. on the first owner's price in any other case. Transport charges and market tolls may be added, and, in the case of home-grown Apples, certain charges set out in the Order for the use of packages may also be made.

BOYCOTT OF GERMAN SEEDS.

THE proceedings at the annual meeting of the Agricultural Seed Trade Association, held at the Great Eastern Hotel on the 9th inst., was both interesting and lively, and there was a fine spirit abroad which augers well for the future. Under the presidency of Mr. G. P. Miln, many questions relating to reconstruction were discussed, and it was agreed that whatever method of seed testing was finally decided upon, it should be one that would satisfy not only Great Britain but also the Continent and America, and that certificates of germination and purity should be issued by one British station just as in pre-war days they were issued authoritatively from Zurich.

Mr. Miln, who was re-elected President, said the Council advised that discussion on the question of trading with the enemy should be deferred until the peace terms became known, but the meeting considered otherwise, and amid great enthusiasm it unanimously passed a resolution "That members of the Association should have no business dealings with Germans or German associations for five years after the signing of peace." As some members expressed a desire to extend the period it was suggested that the term might be renewed at the end of the five years.

THE NATIONAL FEDERATION OF FRUIT AND POTATO TRADES' ASSOCIATIONS.

ON and after December 6, 1918, the offices of the National Federation of Fruit and Potato Trades' Associations (Incorporated), Ltd., will be transferred to 34/35, Southampton Street, Strand, London, W.C. 2.

HORTICULTURAL ADVISORY COMMITTEE.

THE Horticultural Advisory Committee appointed by Mr. Prothero is empowered to advise him on all matters connected with the industry. The actual terms of reference are: "To advise the Board of Agriculture and Fisheries on all questions connected with the promotion of market gardening, fruit growing, and horticulture generally, and in particular with regard to the distribution of produce and the organisation of the trades connected with these industries in the situation created by the war." The main advisory committee has appointed special sub-committees to deal with various branches of horticulture either separately or by joint session. These sub-committees are.—1. Production: (a) Fruit Sub-committee; (b) Market Garden Sub-committee; (c) Nursery Sub-committee; (d) Flower-growing Sub-committee; (e) Glass-house Sub-committee. 2. Distribution. 3. Education and Research.

BI-COLOURED CHRYSANTHEMUM: *R. O.* Instances are not rare where a Chrysanthemum flower has reproduced its varietal colour on one half of its area and a distinct colour on the other half. In the example sent, of W. H. Thorpe, one half is white, and the other half dull red.

CULTIVATION OF MEDICINAL PLANTS: *C. H. L.* The Royal Horticultural Society publishes a booklet on medicinal plants, price 4d.

FAILURE WITH CHRYSANTHEMUMS: *E. C.* An examination of the specimens sent fails to show any disease or pest, therefore the failure must be due to some error in cultivation or some local influence, which can only be determined by a careful examination on the spot. A slight escape of gas working through the soil into the house might be responsible for the trouble, but the presence of gas would be readily detected. Whether an escape of gas, or the presence of sulphur fumes from a furnace is the cause of trouble, the escape is a slight one, as a large amount of either coal or sulphur gas would cause rapid defoliation. Has the house been painted recently, or has creosote been used in it?

NAMES OF FRUITS: *W. F.* Dumelow's Seedling. —*T. D.* 1, Bramley's Seedling; 2, Lane's Prince Albert; 3, Winter Greening; 4, Emperor Alexander; 5, Northern Greening; 6, not recognised, probably Flat Nonpareil.—*W. B.* 1, Round Winter Nonesuch; 2, Brabant Bellefleur (syn. Iron Apple).

RICHARDIA (ARUM) LEAVES DISEASED: *W. H. S.* The plants are affected with a disease known as soft-rot of Calla. Frequently the disease develops so rapidly that the leaf rots off at the base before it has time to lose its green colour. If the conditions for the development of the disease are favourable after the corms are affected, the softened spots will become dry and darker in colour. In these spots the disease may remain dormant until the conditions are favourable for its further development. In this way the complaint is carried over from season to season. The cause of the disease is a minute bacteria called Bacillus aroideae. There is no known cure, but the disease may be kept in check by changing the soil and selecting only healthy plants for stock.

FIG. 97.—A BI-COLOURED CHRYSANTHEMUM.

Obituary.

Sir Charles Dilke.—We regret to announce the death of Sir Charles Wentworth Dilke, son of the late Sir Charles Dilke, at Brighton, on the 7th inst. He spent a great part of his life in foreign travel, especially in Australia and New Zealand. He was President of the Hove Allotment Holders' Association, and was a great lover of nature, especially of bird-life. He was only forty-four years of age.

ANSWERS TO CORRESPONDENTS.

BASIC SLAG FOR FRUIT TREES: *G. F. C., North ants.* A suitable dressing of basic slag for fruit trees would be 3 ozs. to the square yard of rooting area, which may be roughly estimated by determining the spread of branches and allowing 1 foot or rather more all around as the limit of the fibrous roots. After the slag is applied, very lightly fork the surface soil, taking care not to injure the roots. This fertiliser is slow acting, and not of a caustic nature, therefore it is not so necessary to keep strictly to the quantity advised as in the case of most concentrated manures.

SEEDS FOR BELGIAN CIVILIANS: *A. O. M.* Apply to the Royal Horticultural Society, Vincent Square, Westminster, stating your case and what you are prepared to do by way of help. Possibly help may be afforded through the War Horticultural Relief Fund.

SEABROOK'S BLACK CURRANT: *H. B. W.* The variety of Black Currant known as Seabrook's Black was introduced by Messrs. W. Seabrook and Sons, The Nurseries, Chelmsford.

A WHITECHAPEL BOTANICAL GARDEN.

"THE most vivid imagination can hardly picture a botanical garden in the Whitechapel as we know it to-day. Nor is there any record of such an establishment in any of the histories of that part of London which I have consulted. Even Lysons, who dealt very fully with the gardens of the metropolis during the eighteenth century, is silent with regard to any horticultural feature of the district. It is true that Whitechapel is one of the few parishes in London which is almost entirely devoid of historical annals. It has, nevertheless, always been a busy place. In 1778 Noorthouck, in his *History of London*, describes Whitechapel as "a fine wide street, and is the principal eastern entrance into London from the great eastern road. The south side of this street is used for a haymarket three times a week; it is no less a market for meat, being crowded with the shops of carcase butchers on that side all the way for some distance beyond the bars." There were many inns, and "stage coaches to the neighbouring villages ply at all hours of the day."

There were doubtless here, as in all other rural suburbs of London, many gardens attached to large houses, and market gardens in considerable numbers, up to the beginning of the last century. That there was in Whitechapel a garden of a very special and interesting character is proved by a sale catalogue which has just recently come into my possession—a catalogue which is as rare as a book from the press of Caxton! It is a mean-looking little pamphlet of six leaves, somewhat cropped in binding but perfect as to text. The title-page reads: "Catalogue of a Compleat Collection of Plants, Shrubs, and Fruit Trees: Consisting chiefly of valuable Exotics, beautiful flowers, and a large number of Pines in full Fruit and succession; also Garden Chairs, Frames and Utensils, of Mr. WILLIAM BENNETT, Cornfactor and Biscuit Baker, Deceas'd: which (by Order of the Executrix) will be sold by Auction, By Mr. Langford & Son, on Thursday the 27th of this Instant, March 1766; at the Garden, in Whitechapel Fields, next the half-way House, leading to Stepney." After some details as to viewing and whence catalogues may be had, there is an N.B. stating that "Part of the Exotics are in a lesser Garden of Mr Bennett's, near Coal Stairs, Lower Shadwell."

Who was William Bennett? Unfortunately, beyond the statement that he was in business as a cornfactor and biscuit baker, I have been unable to find out anything about him. I had hoped to discover his will at Somerset House; but the only will of that name or period I could discover was one dated January 14, 1765, of William Bennett of Stratford Langthorne in the parish of West Ham, Essex, described as "gentleman," who appears to have been a man of considerable wealth for the time; but there is nothing in the will to lead me to identify him with the cornfactor and biscuit baker. On the other hand, the word "Executrix" on the title-page suggests that there was a will. The fact that the leading firm of London auctioneers, Langford & Son, of the Grand Piazza, Covent Garden—the rooms formerly occupied by Cock, the James Christie of his day, and the friend of William Hogarth, the artist—conducted the auction, is evidence that the sale was regarded as an important one, as it was one of the earliest of its kind to be held in the neighbourhood of London.

The contents of the garden are catalogued in eighty-two lots, and each lot varied in number up to thirty or more plants. The lots were obviously arranged to attract the small amateur gardener, of whom there would probably be many in the neighbourhood. The remarkable fact about the sale catalogue is the approximately accurate botanical character of the nomenclature, a convincing proof that the plants must have borne their names, and that William Bennett's interest was at least as much botanical as horticultural. It is also evident that Bennett attended very scrupulously to the naming of his plants, or the auctioneers would never have been able to undertake the cataloguing in the manner in which we see it done in this list. There were two hot-houses—what we should now term stove-houses—the upper or larger, and the lower or smaller. There were also two greenhouses, and a "little Hot House," in the "Lower Garden," which was probably the one near Coal Stairs, Lower Shadwell, already referred to. It is noteworthy that of many of the plants which were rare in this country a century and a half ago Bennett's garden contained several specimens distributed in the various lots.

I have extracted and arranged in alphabetical order most of the botanical names given in the catalogue, with such corrections and the accepted names of to-day as appeared to me to be necessary in parentheses. The list is as follows: Aloe (= Agave) vivipara, Amonium plinii, Baccharis ivefolia (= Conyza viscidula), Bixa Orellana, Bosia yewa mori (= Bosea Yervamora), Cedrelia (= Cedrela) odorata, Celastrus nervosus, Cereus grandiflora (= grandiflorus), Clitoria Ternatea, Coriaria myrtifolia, Coronilla valentia (= valentina), Cotyledon hemerspericum (= hemisphaerica), Crassula perforata, Dracontium pertusum (= Monstera pertusa), Euphorbia padifolia (? = E. Caput-Medusae), Euphorbia junusfolia, Frutex quercifolia, Haemanthus coccineus, Hibiscus Abelmoschus, Hibiscus subdarissa (= sabdariffa), Hibiscus hirtus, Hibiscus mutabilis, Ledrum (= Ledum) palustre, Lotus erectus, Menispermum similis (? = smilacinum), Mercurialis tomentosum, Mula tridentata, Parkinsonia aculeata, Pisonia aculeata, Polypodium aureum, Psoralea, Rivinia glabra (? = Rivina humilis), Ruellia ciliata, Ruscus andro-

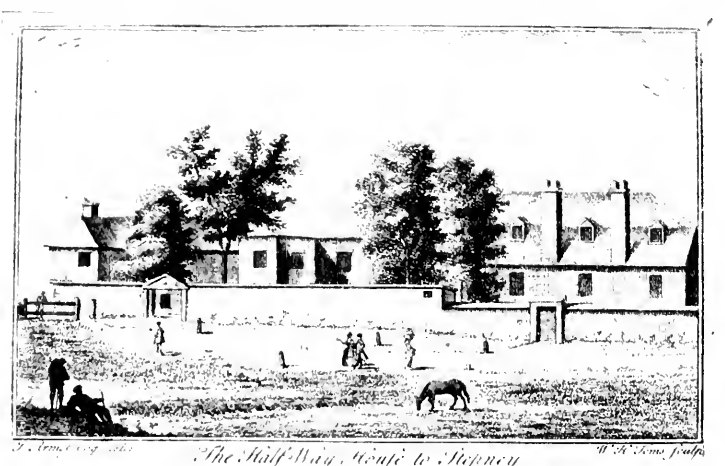

FIG. 78.—THE HALF WAY HOUSE NEXT TO BENNETT'S GARDEN AT WHITECHAPEL.

gynus (=Semele androgyna), Selega (=Solago) spuria, Solanum sodomum (=sodomeum), Spiraea frutex, Stapelia hirsuta, Urena lobata, Viburnum dentatum, and Volkameria inermis.

It will, I think, be admitted that the list is a remarkable one for the time and place. Many of the plants were of comparatively recent introduction, and at least three were grown by Bennett years earlier than the dates recorded of their introduction into Great Britain. For instance, 1779 is given in most books as the date of the appearance of Solago spuria in English gardens; and 1806 as that of both Pisonia aculeata and Ruellia ciliata, yet both these were cultivated by Bennett at Whitechapel forty years earlier. As it may be assumed that his garden was established many years before his death in 1766, it is reasonable to assume that Bennett was one of the first, if not the earliest, to grow Viburnum dentatum (1763) and Ledum palustre (1762), and possibly Monstera pertusa (1752). The Widow-wail, Cneorum, was also grown by him, although 1793 is the date given of the introduction of the first two of the species to find a place in our gardens.

Having given a selection of the botanical names, it will perhaps be interesting to quote a few of the popular ones under which Bennett probably received and certainly grew some of his plants, many of which perhaps had not yet received botanical baptism. We find such names as Anotto (Bixa orellana), African Asparagus tree, Barbadoes Gooseberry, Bonduc or Nicker tree, Bengal Fig, Canary Lavender, China Rose, Cochineal Fig, Cornish Bird-cherry, Cotton-tree, Fiddle-wood, Egyptian Arum, Guinea Hen-weed, Hedgehog Aloe, Horse-shoe Geranium, Ketmia (obviously the English form of the French name Ketmie for Hibiscus), Indian Reed, Jack-in-a box, Persian Cyclamen, Papaw Tree, Physic Nut, Sandbox Tree, Sponge Tree, Tacamahaca, Torch Thistle of Surinam, Toothache Tree, Viva poca, a sort of Andromeda, and Widow-wail (Cneorum), to mention only a few.

It will be noticed that the exotics are not from any one particular part of the globe but from all countries, tropical and otherwise. Living near the port of arrival of all the great merchant ships from the Indies and other parts of the world, Bennett would have had special opportunities of adding to his collections. It is perfectly certain that his garden would be well known to such men as Philip Miller, of the Apothecaries' Garden at Chelsea, as well as to his near neighbour, James Gordon, the famous nurseryman, of Mile End, and probably also to such rich enthusiasts as Peter Collinson and Richard Richardson; it is possible that some reference may be found in the unpublished and voluminous correspondence of the latter to Bennett, but nothing appears to be in the selection printed by Dawson Turner in 1835. So far, then, the name of William Bennett is an entirely new one in the annals of English horticulture. Although his business was that of Corn factor and biscuit baker, there is just the suspicion that Bennett was not exclusively an amateur gardener. The first four lots in his sale rather suggest that he also traded in plants, for they consisted of over 350 Pineapple plants in fruit, succession plants, crowns, suckers, and stumps.

The sale catalogue is precise in stating that Bennett's garden was in Whitechapel Fields, next the Half-way House (clearly a landmark), leading to Stepney. In Rocque's map of London, 1746, the Fields are shown contiguous to the Mulberry Gardens, obviously one of the many country resorts of the citizens of the eighteenth century. According to the map in Baldwin's "New Complete Guide," 1766, the Fields occupied a broad space on the south side of Whitechapel Road and Mile End, and extending east from the London Hospital down nearly to Ratcliff Highway. From the Crace Collection in the British Museum I have obtained photographs of two contemporary prints. In the one reproduced in fig. 98 we get an interesting aspect of the East End in its rural days, with the Half-way House mentioned as being next to Bennett's garden. It was probably the residence of some City magnate. The other print, reproduced in fig. 99, shows a portion of the Fields partly taken up with a camp, and it may be that Bennett's garden and house were situated somewhere in the distance. At all events these two views help us, if not to reconstitute Bennett's garden, to get some idea of its atmosphere and immediate surroundings. With its crowded streets and alleys it would to-day be a very difficult matter to locate the exact spot of the Whitechapel Fields of a century and a half ago. *W. Roberts.*

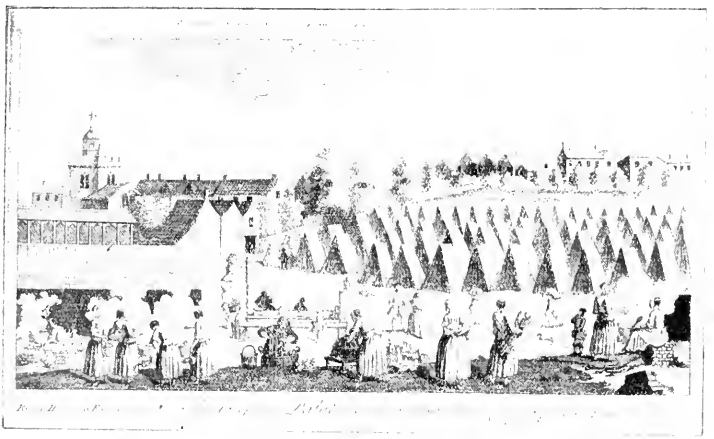

FIG. 99.—CAMP IN WHITECHAPEL FIELDS.

ORCHID NOTES AND CLEANINGS.

ODONTOGLOSSUM CRISPUM RAGGED ROBIN.

A FLOWER of this magnificent and distinct form of Odontoglossum crispum, taken from a plant imported ten or twelve years ago, is sent by Richard Ashworth, Esq. It has all the beautiful points which have made O. crispum a leading favourite in gardens, and its distinguishing features are so marked that it is easily distinguished from other forms, a quality which many varieties cannot lay claim to. The flower is just over 4 inches across, and has sepals 1½ inch wide, white, tinged with violet at the back, and bearing clusters of large reddish-purple blotches in the centre. The petals are 1⅞ inch across, deeply and irregularly fringed at the margin, white, with one or two reddish-purple spots in the middle. The crimped and fimbriated lip is white with a large chestnut-red blotch in front of the yellow crest.

NEW HYBRIDS.

BRASSO-CATTLEYA GENERAL DIAZ.—A charming flower of this new cross between Cattleya Pittiana and Brasso-Cattleya Madame Chas. Maron, is sent by J. Ansaldo, Esq., Rosebank, Mumbles. The influence of Cattleya granulosa in C. Pittiana is shown in the firm substance of the flower and the shape of the lip. The sepals and petals are cream-colour tinged with lilac; the fringed lip is rosy-lilac with yellow lines from the base.

BRASSO-CATTLEYA NICOLO (parentage unrecorded).—This new hybrid is also sent by Mr. Ansaldo. It is a pretty flower, with primrose-yellow sepals and petals, and ample, light rose-coloured lip with pale yellow veining.

HYBRID ORCHIDS.

(Continued from November 16, p. 193.)

Hybrid.	Parentage.	Exhibitor.
Brasso-Cattleya General Diaz	C. Pittiana × B.-C. Madame Chas. Maron	J. Ansaldo, Esq.

* Shown at R.H.S., December 3, as Oda. President Clemenceau.
† Shown at R.H.S., November 19, as Odm. Momus.

WOMEN IN HORTICULTURE.

THE subject of women with respect to their fitness for fresh fields of industry is now being discussed. They have filled a large place in horticulture since the commencement of the war, but it is twenty-three years since women were first employed as improver gardeners at Kew. Swanley College had been training women in horticulture for some time, and two of the most promising were engaged for a two years' course at Kew. The innovation attracted a great deal more public attention than it deserved, owing to the decision that whilst at work the women were to be dressed as boys, and they therefore wore knickers, jacket, and cap. Women continued to form part of the garden staff for about seven years, in which period ten were employed. They were a success at Kew, but only one of them stuck to horticulture and is still a gardener, the others finding some other calling which they liked better. This was not an encouraging result, and as in those days there were plenty of young professional gardeners who were anxious to get into Kew, it was decided that they should have preference.

A difference between the early training of garden boys and these young women, as well as a difference, in some cases a wide one, in their general education, made it difficult to treat them all alike. Still nothing happened to justify any objection on the part of men to the woman gardener, and if she had thought the calling good enough she would have been welcome. But she did not, and notwithstanding all that has happened in consequence of the war she will not now, after she has been through the mill, unless it is made worth her while.

When the men were wanted for war service the women came forward to help to carry on, and Kew was fortunate in securing trained women from the start. Most of them came as war workers, and although the hours were long and the pay low, they showed the right spirit by doing their best, whatever the job was. Some of them were afterwards induced by offers of better pay and shorter hours to go elsewhere, and vacancies had perforce at times to be filled with women who had little or no training. These, however, rendered useful service, and were quick in getting into the gardener stride. A few found the work overheard, whilst all objected to the long summer hours, 6 to 6. A concession was made to ease the long afternoon by a break of half an hour at 4 o'clock for tea. The following year the day was shortened by an hour, work ceasing at 5 instead of 6, but the daylight saving scheme made it necessary for a portion of the staff to return for an hour after tea,* so that really the working day for gardeners was lengthened by an hour during summer. The women then petitioned for a later starting time in mornings, but this they failed to get.

The present working hours, wages, etc., are set forth in the following particulars which were sent to applicants for employment: "During the war women who have received a good training, either at an horticultural college or in a garden of repute, are employed at Kew to replace gardeners who have enlisted. Their wages are 4s. 4d. per day, with a weekly war bonus of 12s. 6d., and 9d. per hour for Sunday duty and overtime. Their hours are: Summer, 6 a.m. to 8; 8.45 to 12; 1 to 5 p.m. Winter, 8 a.m. to 12; 1 to 4.30 p.m.; two Saturday afternoons in three free. Applicants, who should be healthy and strong, unmarried, and between 20 and 40 years of age, must furnish particulars of training, and age, with a testimonial from present or last employer. They are required to live in the neighbourhood of Kew."

The women are keen with respect to what is termed the rights of the worker. Gardeners have hitherto accepted as inevitable long working hours and low wages, and attempts to improve matters have not met with much support. But the women are not so disposed to put up with conditions whose only justification is that they are usual. They are educated, and have been used to the decencies of life. Their influence, therefore, is in an uplifting direction, and for this they are entitled to the encouragement and gratitude of those who have experienced the lot of the average journeyman gardener. I am quite certain these women will not take up gardening as a suitable calling, and be satisfied with the pay, etc., that men have accepted. Employers who expect what is known as polish, education, respectability, gentlemanly manners, etc., in quality with various names as well as skill in horticulture, are likely to find that it is an extra, and must be paid for.

It has been asked whether women are capable of lifting horticulture into a higher place among industrial arts than it has occupied hitherto. The answer to this is that intelligence brains will tell, whatever the sex may be, and horticulture ought to be the gainer, if, as a result of the war, its practitioners are better equipped from the start than they formerly were. The question of physical fitness will not come in when the drudgery of the garden is separated from the art, and, as in the case of other callings, is performed by the strong and unskilled. The handy man, "our gardener," whose duties include much that is not gardening, will always be in demand, and it is unlikely that the women gardener will poach on his preserves. Nor will she compete with the market garden labourer. It is in what we may call the science of horticulture that women may succeed, and in doing so prove a help, not a hindrance, to all-round betterment.

Much will depend upon the early training of young women who desire to become gardeners. The lack of experience of the right kind is evident in most of those who are working as gardeners now. The young man gardener has had four or five years' practical training by the time he is twenty, but there must be objections to starting good class girls of fifteen or so on the same course. It depends on the way girls are taught to view such things. Boys know that as soon as they are old enough they will be put into harness. Hitherto girls whose prospects demanded that they should be able to earn a living have had the factory, shop, or domestic service as a starting board. If they are willing to try the farm and garden as the boys do, they may go through all right and turn out well.

I may be wrong, but speaking from long experience, and an intimate acquaintance with the ups and downs of gardening and gardeners, male and female, I must own to a conviction that unless the conditions are considerably improved, gardening will not hold out good prospects for educated young women. W. W.

* Paid for as overtime.

SOME OF THE NEWER ROSES.

(Concluded from p. 236.)

ROSES INTRODUCED IN 1917.

OF the Roses introduced in 1917 I can speak with less certainty, and I will only say I have good reasons for the suggestions I make. I will take these under the raiser's headings:—

MESSRS. A. DICKSON AND SONS. This firm offers:—

COL. OSWALD FITZGERALD. A beautiful crim-

FIG. 100.—WOMEN GARDENERS AT KEW, 1917.

son Rose of fine size, not large enough for show, but a fine decorative variety.

C. V. HAWORTH. I expect a good deal of this Rose; it is scarlet-crimson in colour, probably good in every way, but not very large nor very full.

DAVID MCKEE.—This I greatly admired: it is of show form, and a deep yellow. It has the Pernetiana fault of dying back in winter, but grows again well.

K. OF K. An almost single, bright velvety-scarlet variety, and an improvement on that good single Red Letter Day.

KOOTENAY.—Said to be a much-improved Kaiserin Auguste Victoria, and if it proves so it will be welcome, though we now have many good Roses of similar colour.

MOLLY BLIGH.—Very promising, large and scented. A pink Rose of good shape.

MRS. FRED SEARL.—Silvery and carmine, very large and quite up to show form.

MESSRS. HUGH DICKSON:—

ETHEL DICKSON. A salmon rose-coloured variety with silvery reflexes; the raisers de-

scribe it as a bedding variety, but it probably is at times up to show form.

GOLDEN SPRAY.—A distinct break: a large, single, yellow Rose of arching growth.

D. M. BARTON. Deep crimson; of fine shape, fair size. A garden Rose of which I expect a good deal.

LILLIAN MOORE. The 1,000-Dollar and Silver Medal Rose. This ought to prove one of the very best yellows, and probably an improved Mrs Aaron Ward.

LUSTRE STANDARD. A crimson single Rose, with yellow anthers. We have few of this colour among the best singles.

MESSRS. McGREDY AND SON :—

GOLDEN EMBLEM (see fig. 101).—This must strongly compete with Lillian Moore for the palm among the new yellow Roses. It is an improved Rayon d'Or in the matter of growth, and it does not lose foliage as Rayon d'Or does.

FIG. 101 ROSE GOLDEN EMBLEM.

GLADYS HOLLAND.—A fine show Rose; buff, shaded yellow, with the outer petals tinted rose. If vigorous enough this should be an acquisition.

MISS WILLMOTT.—An all-round beautiful Rose, sulphury cream; may be first-class if vigorous.

MRS. C. E. SHEA.—Red, shaded rose; likely to be a useful garden Rose. There will be confusion, I fear, between Roses called after different members of the same family.

NOBLESSE. A yellow Rose, tinged rose on the outer petals; very free, and holds its blooms erect. A good garden Rose, and probably at times up to show form.

M. PERNET DUCHER :—

Of the six new Roses brought out by this firm I have no positive knowledge, and I fancy our English growers are mostly in the same position. I myself have planted Mme. Christie Marvel and Raymond. If I had taken another dip in the "lucky bag" I think my choice would have been Mme. Melba Sabatier or Senorita Carmen Serb.

MESSRS. WM. PAUL AND SON have one or two new Roses, of which W. C. Clark (H.T.) seems very promising.

MR. W. EASLEA has a climbing sport to Mme. Abel Chatenay; a dwarf Polyantha, Little Meg, white, sometimes tinted crimson, a seedling, I understand, from Shower of Gold, also Tiny Tim, a coppery pink Rose in the style of Perle d'Or.

Of the older Roses which have been most admired in my own garden, Countess Clanwilliam, Mrs. Vanderbilt, Lady Greenall, Mme. Jules Bouché, Willowmere, Lyon, Mdme. Herriot, Mabel Drew, Duchess of Westminster, Mrs. Amy Hammond, Edith Part, Queen Mary, St. Helena, Cissie Easlea, Rayon d'Or, Mrs. C. E. Pearson, Avoca, Duchess of Wellington, General McArthur, Lieut. Chaure, Mme. Segond Weber, Marquise de Sinety, Melody, Paul Lédé, Mrs. H. Bracklebank, Mrs. R. D. McClure, Pharisaer, and the Teas Alex. Hill Gray, Harry Kirk, Lady Hillingdon, Miss Alice de Rothschild (very fine and good grower), Molly Sharman Crawford, Mrs. Foley Hobbs (grand), Mrs. Herbert Stevens, Mrs. Myles Kennedy and W. R. Smith have all been very fine. *L. C. R. Norris-Elye, Otterby Manor, Louth, Lincolnshire.*

BAUMANN'S REINETTE APPLE.

UNTIL coming here I was familiar only with the name of this Apple. Recognised authorities do not speak highly of its flavour. A small crop last year enabled me to prove that it keeps well into the beginning of the New Year. This season the yield was very heavy—no other variety equalled it in this respect, and the colour of the fruits was exquisite. Such a bright, rich crimson colour I never remember seeing on any Apples before. What a pity it can claim only a second place in flavour. *C. T., Impthill Park Gardens, Impthill.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Tomatos.—Tomato plants should be kept on the dry side to prevent attacks of disease, including mildew. The plants should be grown in a night temperature of about 55°, and must never be exposed to cold draughts. Keep the plants thinly trained to allow light and air to reach them freely, and remove all side-shoots as they appear, but do not cut off many leaves at this season. Remove the fruits as soon as they show signs of changing colour; they will ripen as well in a warm, dry room as on the plants. Top-dress the roots with a mixture of rough, turfy loam and decayed manure. Sow a further pinch of seed of the variety Sunrise to raise seedlings in readiness to take the place of exhausted plants in the spring. Tomatos growing in 3-inch pots should be placed near to the roof-glass; shift them into larger pots as more rooting space is required. Pot moderately firmly in a mixture of sandy loam, leaf-mould, and fine lime rubble. Ventilate the house with care, and endeavour to obtain healthy plants and a stocky growth.

Endive and Chicory.—These salads will be in greater demand as Lettuces become scarcer. If plants are being blanched in frames by covering them with pots or tiles, other plants in the same pits should be protected from frosts and ventilated during the day to prevent damping. Surplus plants may be taken up about a fortnight before they are required for use and placed in a Mushroom-house or other dark, warm place. Tie the outer leaves over the centres of the plants when the foliage is dry, give the roots a good soaking of water, and keep them well supplied with moisture without overhead waterings.

French Beans.—Seeds of French Beans may now be sown more freely with better prospects of success; successional sowings made once a fortnight will maintain an unbroken supply of pods. Use 7- or 8-inch pots and let them be three parts filled with compost consisting of three parts loam and one part manure from a spent Mushroom-bed; make the soil moderately firm. French Beans require plenty of sunlight, a temperature of 65° to 70°, and atmospheric moisture. Give the plants liquid manure when the pots are filled with roots. Dwarf varieties, such as Magpie and Ne Plus Ultra, are best to grow now, while Canadian Wonder is the most useful variety at a later period until the climbing varieties can be sown.

Cucumbers.—Plants in full bearing require liberal feeding and top-dressings, applied little and often, to keep them prolific in cropping and healthy. Stimulating liquids should be weak and various, and if made 10° warmer than the bed so much the better. The material used for top dressing can hardly be too rough; moderately light sandy loam from which the finest particles have been removed, is suitable; this, with lime-rubble and charcoal, should always be kept warmed, ready for use. Maintain a moist atmosphere without direct syringing. The temperature may rise to 70° on mild nights, falling to 65° in colder weather. Ventilate the house a little on bright days, without exposing the plants to cold draughts. Make a further sowing in small pots to raise plants ready for planting out early in the New Year.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

The Cool House.—Some of the plants in the cool Orchid houses, including Odontoglossums, are in full growth, and others are resting. Those which are dormant should be placed by themselves, where they may receive only sufficient water to keep them plump and healthy. Those that are active should be encouraged to make strong, healthy growth. Plants that are developing their inflorescences should be ex-

ASTER AMELLUS.—MR. KING, GEORGE

posed fully to the sunlight in order that the spikes may grow strong and produce flowers of good texture. They should be watched nightly for slugs, which are prone to feed on the young flower-spikes, often as soon as they are observable at the base of the pseudo-bulbs. The insects may be trapped by placing Lettuce-leaves or hollowed-out Potatos on the stages between the pots and on the surface of the compost. A band of dry cotton-wool placed around the base of the flower-spike is sometimes helpful as a protective measure. The house should be vaporised once every fortnight to destroy thrips and aphides.

Odontoglossum. – Odontoglossum Uro-Skinneri, O. luteo-purpureum, and others of their section are developing fresh roots from the bases of the young growths, and any in want of fresh rooting materials may be given attention. These fleshy-rooted plants should not be potted too firmly, and the pots should contain plenty of drainage material. The compost should be very porous: it may consist of three parts Osmunda-fibre, or A1 fibre, and one part Sphagnum-moss, the whole cut up roughly and well mixed with crushed crocks. Only sufficient water is needed to keep the surface moist until the new pseudo-bulbs show signs of swelling, after which the supply of moisture may be increased gradually. Grow the plants in the warmest part of the Odontoglossum house.

Oncidium. Oncidium ornithorynchum has recently passed the flowering period, and the plants should be kept on the dry side for a short time, but as soon as roots are seen to be developing from the bases of the young growths attention should be given them. If the plants are in pots of a suitable size and the compost is in good condition, they need only to be resurfaced with fresh material. Some will require repotting, and for these a similar compost may be used to that recommended for Odontoglossum Uro-Skinneri, but the fibre should be cut into smaller portions. O. cheirophorum, together with O. variicosum and O. tigrinum, are in bloom. When the spikes are cut the plants should be rested in a cool, dry house, affording them only sufficient moisture at the roots to keep the pseudo-bulbs rigid.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Cyclamens.—Young Cyclamen plants which were raised from seed sown in the autumn are ready for transference to larger receptacles. They may either be potted in 2½-inch pots or pricked out into boxes, and the latter method may be preferable, as it entails less labour. The young plants also will not be so liable to suffer a check in boxes as they would if potted. A compost of two parts loam to one of leaf mould, and a liberal quantity of coarse sand, or crushed brick rubble, will provide a suitable rooting medium. See that the boxes are clean and well drained, and make the soil quite firm. Place the boxes near the roof glass in a house having a moist atmosphere, and endeavour to maintain an equable temperature of about 55°. Lightly spray the plants with tepid rain-water twice a day when the weather is fine and damp their surroundings two or three times daily. Should aphis attack the leaves lightly fumigate the house.

Begonia Gloire de Lorraine.—When the earliest plants of this Begonia have finished flowering they may be partly cut back and placed closely together in a house or pit having a temperature of about 45° to rest for a few weeks. The roots should be kept on the dry side during this period. After resting the plants will develop shoots suitable for cuttings much more freely when they are once started into growth again. The later plants will flower during the greater part of the winter if carefully watered and fed. Keep the flower stems neatly tied to their supports or the plants will quickly assume an untidy appearance.

Violets. The weather has been very favourable for Violets in cold frames, and the plants are looking strong and healthy. It has been possible to remove the lights entirely for several consecutive weeks, and this treatment has greatly benefited the plants and has rendered them sufficiently hardy to pass through the remainder of the winter. Continue to give them an abundance of fresh air whenever the weather is favourable. In the event of severe frost cover the glass with mats and litter. Remove decayed leaves regularly and lift the flower buds above the leaves. Stir the soil between the plants with a pointed stick and sprinkle a little well-seasoned soot about the roots. Water the roots in the early part of the day when this is necessary; only a little water will be required for the next few weeks.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

The Strawberry Beds.—Take the first favourable opportunity, when the weather is fine and the soil dry, to examine newly-planted Strawberries. Tread lightly around the crowns to make the plants firm at the roots, for they may be lifted out of the soil by severe frosts. After removing weeds, hoe the soil between the plants. When these details have been carried out the plants will not need much further attention for months to come. Replace weakly plants by stronger specimens from the surplus stock. Alpine Strawberries are very promising, and I do not see a weakly crown amongst our plants. The older beds of Alpine varieties may be top-dressed with well-decayed leaf-mould after it has been passed through a coarse sieve. Other Strawberries may be treated in a similar manner, but for these we use well-rotted manure in preference to leaf-mould, breaking it down somewhat when it is put on the beds; do not cover weeds with either the leaf-mould or manure.

Material for Top-Dressing. Procure some good soil, i.e. fading that, well-rotted manure, in readiness for use as top-dressing as soon as the work of pruning is done. It is not essential to fork the material into the soil at the time of application; possibly it may be more convenient to apply it when the ground is somewhat hard with frost and to spread it later. For preference use a little fresh loam for Cherries and Plums, having first applied a moderate dressing of a concentrated fertiliser suitable to stone fruits; that is, one containing plenty of phosphates and potash. Lightly fork the fertiliser into the soil before the top-dressing of loam is applied. When dealing with Apple trees examine the roots to see if American Blight is present, and if the pest is detected apply a soil disinfectant freely, and cover it with soil at once. Remove all suckers in the case of all trees. Trees that are planted against walls with south aspects may need watering.

The Fruit Room. Fruit is keeping quite as well as usual, and the small quantity must be used with great economy to make it last as long as possible. Fruit intended for rail transit should be packed with great care. Paper shavings are as good as any other material for packing, and moss, when dried and carefully picked over, is also suitable. When the temperature drops suddenly use means to exclude frost from the fruit-room.

FRUITS UNDER GLASS

By W. J. GRISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

The Cherry House. The roots of Cherry trees planted in inside borders should be kept thoroughly under control by taking out a trench about 4 feet from the main stem, and refilling it with fresh loam. In this way a mass of fibrous roots is formed near the surface, but unless the trees have grown too vigorously it is not necessary to prune them. Very little branch pruning is required beyond reducing the summer-pruned side shoots to two or three buds. Before the borders are top-dressed with fresh calcareous loam thoroughly cleanse the house and wash every branch carefully with a suitable insecticide. Ventilate the house freely or the trees will be hastened into growth unduly.

Early Peaches and Nectarines. There will be no difficulty in retarding the earliest pot trees of Peaches and Nectarines for at least another month. In the meantime, let the trees be well exposed to the light, in a cool, airy house, and on no account use fire-heat except in times of frost, when only sufficient should be used to prevent injury from extreme cold. The early permanent trees will be greatly benefited by a long period of rest, but it must be borne in mind that where it has been the custom to start the house early, the roots become active, and the trees swell their buds in the absence of fire-heat, and especially during mild weather. A little warmth in the pipes then becomes essential, but until the flower-buds show colour the night temperature should not exceed 45°. For the present ventilate the house freely, both day and night, and continue to do so for so long as mild weather prevails.

The Forcing Houses.—As there is not sufficient fuel to force fruits very early, advantage should be taken of the opportunity to get the houses thoroughly cleansed, painted and repaired. Where several houses are heated from one boiler it is advisable to have screw-plugs inserted in the pipes in order that they may be emptied of water in times of frost.

Manures.—As it becomes increasingly difficult to obtain farmyard or stable manure from outside sources, the best use should be made of all garden refuse. Any animal manure to be had should be well mixed with fallen leaves, lawn mowings, turf edgings, decomposed vegetable matter, wood ash, house sewage and garden refuse. It will greatly add to the quality of the compost if the heap is saturated with manure-water after each turning. Failing good farmyard manure such a compost provides the best substitute for mulching fruit borders.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

Frame Stock.—Should severe frost set in it may be as well to remove Calceolaria amplexicaulis and large-flowered Pentstemons from frames to a structure from which frost may be excluded. The former plants will, no doubt, be rooted, and should not be over-watered. The latter occasionally is slow to root, and should rooting be not effected, the soil in the boxes must still be kept moist. Damp in frames is very injurious to hardy stock, and always enough air should be admitted to neutralise its effects. Any green surface growth should be removed, and some clean sand which has been heated for a few hours, hot enough to sterilise it, scattered evenly among the cuttings. Common Paris Daisies and Marguerite Mrs. Sander should not be left longer in the frames. Although not yet rooted there need be no fear that they will not root before long.

Work in Wet Weather. The horticultural sundriesman, while lightening the labour of the garden to a great extent, has at the same time spoiled workmen for many jobs which he at one time was expected to do in bad weather, and did before the former's advent. At this period of the year the stock of garden baskets was renewed, labels of all sorts made with knives, and permanent labels rewritten, or more probably "printed," in bold characters. Flower sticks also were whittled to a nicety as supports for Heaths, Achimenes, and Pelargoniums, and painted, and stored. Now, probably, the only kind of work of this nature that is continued is the tying of mats and the making of Birch-brooms. It was not unusual, too, to repaint the inside woodwork of vineries, and some lads were adepts at all these little jobs, which served to pass many dreary days in a pleasant manner. I think it not unlikely that even this present winter some of these jobs may have to be carried out at home. Seeds, where they have been saved, will need cleaning and placing in bags or boxes, with name and year of growth. Several plants were late in ripening seeds. Hollyhocks and Tritomas did not mature here at all, but they finish nicely indoors, and, indeed, I have a lot of young autumn-sown Hollyhocks growing well from seeds which were sown quite green. Mould must, however, be guarded against in the case of immature seeds by keeping them absolutely dry and spread out thinly, so that they do not heat. Usually, too, at this time, Pelargoniums in boxes must have their withered leaves removed. They may induce damping of the stems if left, especially when fire-heat is only used to preserve the plants from frost.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* EDITORS, 41, Wellington Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38.5°.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, December 18, 10 a.m.: Bar. 30; temp. 48°. Weather—Dull.

Fresh Vegetables as Preventives of Disease.

In spite of the fact that it is now proved beyond question that all risk of scurvy may be prevented by proper dieting, outbreaks of scurvy have occurred recently at various times among His Majesty's Forces at home and abroad. Hence the Food (War) Committee of the Royal Society has done well to issue a memorandum on the Cause and Prevention of Scurvy. The memorandum, which summarises our knowledge on the subject, should be in the hands not only of all medical men, but also of all housewives.

We have in this journal already published the essential facts relating to the cause of scurvy, but in view of the great importance of the subject they will bear repetition.

Scurvy is a "deficiency" disease; that is, it is due to the absence from the food of a certain definite substance. This substance is known as an accessory food substance, or vitamine. The vitamine, which is the natural preventive medicine which protects the body against scurvy, is contained in greater or smaller quantities in *fresh* food. Oranges, Lemons, and fresh green vegetables contain large quantities of vitamines. Fresh vegetables, such as Swedes and Potatos, contain considerable quantities, and fresh meat and milk contain small amounts.

Dried and preserved foods contain little or none. Vitamines are very sensitive to heat—the longer food is cooked the more the vitamines which it contains are destroyed.

Stewing, for example, causes the destruction of vitamines, and, therefore, such vitamine-containing articles of diet, as Potatos, should not be prepared for table by stewing, but should be cooked quickly, as, for instance, by rapid boiling.

The common practice of adding soda during the cooking of vegetables should be abandoned; for although the colour may be improved, the vitamines contained in the vegetables are destroyed by it.

Perhaps the most interesting point made in the memorandum is the fact that West Indian Lime juice as ordinarily prepared is, despite the common opinion to the contrary, useless as a preventive of scurvy.

The belief that it is a preventive is due to the fact that the so-called Lime juice which was used successfully in the Navy in the first half of the 19th century as a preventive of scurvy was not Lime juice at all, but Lemon juice obtained from the Mediterranean region. In Nares' Arctic expedition Lime juice prepared from West Indian Limes was substituted for the first time for Lemon juice, with the result that serious outbreaks of scurvy occurred.

The great value of Oranges as a means of protecting the body against scurvy deserves to be widely known. Although it has been stated above that vitamines are very sensitive to temperature, it should be remembered that it is the *time* of cooking rather than the temperature which affects these anti-scorbutic accessory food bodies. The longer the cooking, the more the vitamines are destroyed. Hence, where Potatos have to be relied upon to provide most of the winter vegetable diet, they should be cooked by plunging into boiling water, and the boiling should be continued for not more than 20-30 minutes.

Dried Peas, Beans, and Lentils, although rich in food, contain no vitamin s; but if they are soaked in water for 24 hours the vitamines reappear as germination begins, and therefore after this treatment their value as protectors against scurvy is great.

Finally, it should be remembered that deficiency of vitamines, even though it may be not great enough to cause scurvy, may lead to general weakness and lowered vitality. It is therefore desirable in the interests of the people's health that the national diet should consist of large quantities of fresh vegetables, and that supplies of vitamine-containing articles of diet should be available throughout the year.

Coloured Plate.—The varietal forms of Aster Amellus constitute a group of charming autumn-flowering plants of unquestionable hardiness; they are of great value in the herbaceous border, and very suitable for the supply of flowers for cutting. Among the numerous varieties, King George, which forms the subject of our coloured Supplementary Illustration, occupies a very high position. It has a very neat habit of growth, and with good cultivation there is no difficulty in obtaining specimens a yard in diameter. Such plants present a fine picture during September when covered with bright purple-blue flowers, each measuring from 2½ to 3 inches in diameter. The golden disk enhances the attraction of the blooms, but to some artistic tastes the flowers are even more attractive when, several days old, the disk has turned to a bright mahogany tint. Aster Amellus King George received the Royal Horticultural Society's Award of Merit on September 8, 1914, when shown by Mr. AMOS PERRY. Both in gardens and in the flower markets this handsome perennial Aster has already become very popular, and American growers have also recognised its great value.

The Wheat and Potato Crops. — The total production of Wheat in Spain, the United Kingdom, Italy, Luxembourg, Netherlands, Switzerland, Sweden, Canada, the United States, India, Japan, Egypt, and Tunis is estimated at 1,073,027,000 cwts., or 18.1 per cent. above last year, and 7.1 per cent. above the average of the five years 1912-16. The Australian Wheat production for 1918-19 is estimated at 43,305,000 cwts., or 29.9 per cent. below 1917-18, and 26.8 per cent. below the average of the five years 1912-16. The yield of Potatos in France, Great Britain, Italy, Luxembourg, Sweden, Canada, and the United States is estimated at 579,031,000 cwts., or 11.1 per cent. below last year's production, and 4.0 per cent. below the average of the five years 1912-16.

Chamber of Horticulture.—Lieut. JOHN F. GOAMAN (late 3rd Royal Berks.) has been appointed Assistant Secretary (Statistics) to the Chamber of Horticulture. The Secretary informs us that the office of the Chamber will be closed from December 23 to 29 inclusive.

The Home Seed Industry.—At the annual meeting of the Agricultural Seed Trade Association of the United Kingdom, held on December 9, and presided over by Mr. G. P. MILN, to which we referred on p. 244, the desirability of providing a Diploma for those engaged in the highly technical work of seedsmen was advocated. Gratitude was expressed by the chairman for the assistance rendered by the Food Production Department in obtaining exemptions for the essential experts, and he also expressed the belief that this country could become less dependent on foreign sources of supply than in the past, as, for example, by growing certain agricultural grass seeds for which there is a large demand both here and abroad. Too much reliance had previously been placed on German sources of supply, and there is no reason why experiments in growing for seed such grasses as Rye grass, Cocksfoot, Meadow Fescue, Timothy, Meadow Foxtail, and perhaps the Poas should not be made in suitable districts of Great Britain. The members of the seed trade have put in unstinted measure their time and energy at the disposal of the State, and by this action have not only rendered invaluable assistance to the State but also conspicuous service to the general community. At the annual dinner held after the meeting it was announced that the President of the Board of Agriculture had appointed Mr. LAWRENCE WEAVER, C.B.E., formerly Controller of Supplies in the Food Production Department, to act as temporary commercial secretary of the Board. In this capacity Mr. WEAVER will be in charge of reconstruction measures for the better organisation of the commercial side of agriculture, and will supervise the provision of cottages and other buildings on small holdings and farm colonies required for the settlement of ex-Service men on the land. The announcement of this appointment will be generally welcomed, for Mr. WEAVER has, in his capacity as Controller of Supplies, shown administrative abilities of the highest order. By his clearness of vision, resolution and energy he has carried out the difficult and intricate work of controlling agricultural supplies with such remarkable success that the Board is to be warmly congratulated on having secured his services for the not less important work of reconstruction.

Women Land Workers Endow a Hospital Bed.—At the recent exhibition in aid of the Garrett Anderson Hospital for Women, the Land Army was responsible for one of the stalls, and as the result of an effort to raise money for a special Women Land Workers' Bed over £200 was obtained.

Official List of "Immune" Potatos for 1919 Planting.—The Food Production Department

has issued a list of varieties of Potatos tested and approved as immune from Wart Disease. Copies of the list may be obtained free, on application, from the Department at 72, Victoria Street, S.W. 1. The only early variety in the list is Edzell Blue. The second early varieties include King George, Great Scot and The Ally. Among the maincrop and late sorts are Abundance, Tinwald Perfection, Dominion, The Lochar, and Templar. All the foregoing maincrops and lates are white rounds or ovals; the following are coloured rounds: Kerr's Pink, Rector, Irish Queen, Shamrock, Flourball, Langworthy, Golden Wonder, and Majestic. Many classes of soil "gives Edzell Blue, first early; King George (seed of which should be sprouted), Great Scot, and The Ally, second earlies; and Tinwald Perfection, Kerr's Pink, Majestic, The Abundance types, Lochar, Golden Wonder, and Langworthy, maincrops and lates.

Chrysanthemum Bronze Molly. — The new variety of single Chrysanthemum illustrated in fig. 102 is a sport from Molly Godfrey, which it resembles in all other respects save colour. The ground-colour of the florets is yellow, and this is suffused with carmine, giving the effect of a golden-bronze hue. The variety received

FIG. 102.—CHRYSANTHEMUM BRONZE MOLLY, A GOLDEN BRONZE SPORT FROM MOLLY GODFREY (R.H.S. Award of Merit, December 7, 1918.)

of the varieties tested at Ormskirk and included in this list are new, and difficult to obtain. Therefore the more important varieties known to be on the market in quantity are indicated in the official list by black type. Many of the varieties, moreover, are practically synonymous, and this is also pointed out in the list, where details are available that will enable the grower to select according to his requirements and to identify different varieties by the shape, colour, eye, haulm, flower, etc. A short selection of varieties recommended for planting "on most the Royal Horticultural Society's Award of Merit on the 3rd inst., when exhibited by Messrs. W. J. GODFREY AND SON.

Fire at a Nursery. A fire which occurred at Messrs. PERRY'S Hardy Plant Farm at Enfield about ten days ago did a great deal of damage. The potting sheds, cart sheds and stables were completely gutted, and a valuable horse was killed. In addition large numbers of Liliums, Trilliums and other plants were destroyed. With the exception of the plants the property was insured.

Land Settlement.—The Committee appointed last March by the Minister of Reconstruction, under the Chairmanship of Mr. LESLIE SCOTT, K.C., "to consider the steps and conditions necessary to attract to employment on the land all returning soldiers and sailors who may wish to take up country life, and particularly to induce them to do so in sufficient numbers to secure the maximum output from the land," has just issued its report. We think the Committee is wise in recommending certain measures that will secure better social conditions and introduce added interest to life in the country, such as the establishment of halls, women's institutes, recreation grounds, and better arrangements for passenger transport to neighbouring towns and villages, and, on the economic side, the provision of good gardens and allotments, common pasture, electric supply, and the general encouragement of rural industries. The Committee recommends the immediate appointment of an Executive Committee composed of representatives of the three War Departments, the Board of Agriculture, the Ministry of Pensions, the Ministry of Labour, and also of the chief voluntary organisations interested in the subject, to disseminate the necessary information, to ascertain who want to take up life on the land, and to make arrangements for the placing of the men, and, where they are inexperienced, for their training. With regard to housing, the Committee urges that the provision of a sufficient number of good houses with gardens is absolutely essential; that the responsibility of finding the necessary capital should be assumed by the State, and that the county councils should be made responsible for providing sufficient houses for ex-soldiers and sailors. It is recognised that simple, cheap, and expeditious machinery is needed for the acquisition of the land, and suggest that the county councils should be the acquiring authority with powers to devise to the parish council. The Committee expresses its opinion in favour of the system of agricultural credit now in course of introduction by the Agricultural Organisation Society.

News from Belgium. We have received from Monsieur LOUIS GENTIL, the curator of the Jardin Botanique de l'Etat at Brussels, a letter containing news of Belgian horticulture, from which we give the following extracts: "England has been marvellous; without England and America we should all have died of starvation here. I was not very stout before, but I have lost 23 lbs. in the last four years. The *Tribune Horticole* decided to hibernate during the German occupation, but we shall start it again when we can; just now it is impossible. Belgian horticulture has lost many of its prominent members among others MM. JULES HYE DE CROM, EDGAR WALTET (the Orchid grower, one of the promoters of the Ghent Quinquennial Exhibitions), FIRMIN DE SMET, and FRED. BURVENICH, père. M. JOSEPH DE HEMPTINNE was condemned to death by the Germans, but was pardoned and sent to prison in Germany. Messieurs A. CUYPERS, TOEFFART, and WYTTENDAELE were deported to Germany. M. JULES DE COCK has been living in France, his two sons, LUCIEN and ANDRÉ, keeping the nursery going. In winter they heated the houses with fires fed by Laurel heads! In Brussels, two notable nurserymen, Monsieur STEEMAN and Monsieur VAN DIEVOET, have died. The last month, November, was the most terrible of the whole war for destruction by bombardments. Thousands of glasshouses were destroyed or rendered useless. On the last day of the German occupation of Ghent, M. FRANÇOIS SPAE'S splendid nursery at Melle was destroyed, and the same thing happened to M. F. PAUWEL'S at Meirelbeke. Nearly all the glass was broken, and the Orchids buried beneath the glass, with the temperature at 6° below zero. M. PYNAERT'S nursery at La Pinte also suffered. M. ARTHUR DE SMET has worked splendidly. He is the president of the Nurserymen's Association, and he and Monsieur CALLIER (the presi-

dent of the Royal Horticultural and Agricultural Society) have saved horticulture from complete destruction. Their work throughout the occupation would fill a book. In Brussels itself horticulture has done pretty well—florists and nurserymen have done good business, and vegetable and fruit growers have made small fortunes! The Orchid growers have thrown away all but their rare specimens, but M. LAMBEAU'S collection is nearly all saved, and so is M. PEETERS'. We shall start our monthly meetings here and at Ghent as soon as possible. Here are specimens of a few prices during the occupation: An egg, 2s.; 2 lbs. butter, 40 francs; a choice Apple, 5 to 8 francs; 2 lbs. Pears, 10-12 francs; 1 Pear, 2-4 francs; 2 lbs. meat, 20-25 francs; 2 lbs fat, 35-40 francs; 2 lbs. grain to make flour, 12 francs; 2 lbs. Grapes, 10-12 francs, against 3d in September, 1914; 1 box of matches, 2½d., against 20 boxes for 1d in September, 1914. The botanical garden has suffered greatly—seven houses had to be emptied, as there was no coal wherewith to heat them, and a lot of rare plants have been lost. I could go on writing indefinitely, but must conclude, before I weary you, with 'Three cheers for England and liberty!'" *Louis Gentil.*

CONFESSIONS OF A NOVICE.

THE character in fiction which most holds my regard and affection is the French curé—or is it abbé—of *Les Misérables*, who entertains with perfect hospitality the thief of his most cherished silver spoons. I should like to think that I should be capable of similar magnanimity toward him who stole my Apples. When all other fruit trees of the neighbourhood failed mine bore wonderful crops. Fearful lest the wasps should spoil them, I bagged the fruits. This was their and my undoing. For the Ministry of Food having offered a price for Blackberries, the unoccupied land bordering on my garden was invaded by all manner of pickers. Among them were some who knew only too well that Apples improve Blackberry pie, and idealists seeking always for the best, and doubtless supposing that the bags indicated that the Apples were ready packed for transport—they robbed me as I had robbed the wasps. If I were to complain it would be of the unsportsmanlike way in which they did things by halves, for half the fruit was carried away one night, and whilst I rejoiced at the moderation of these nocturnal visitors they returned and carried away the remainder. I must confess that the police were very sympathetic when I informed them of my loss. They gave me to understand that it was a bad fruit year, that Apples were in great demand, and that they would probably be controlled. Thus the forethought which, thanks to the timely advice for which this journal is so invaluable, had led me to spray and thereby save my fruit was not wholly unavailing, for someone reaped where I had sown, and though the fruit was unripe, the act of stealing supplied no doubt the sweetness which the green Apples lacked. Otherwise the history of this garden has been uneventful: the Celery has as usual developed spot, and the Cabbages are as clubbable as even Dr. Johnson could desire; my transplanted Onions, obtained from heavy land, died in my light soil—they bowed down and died during the cold and drought of early spring; last, and heaviest sorrow of all, the white pig, which never seemed to take kindly to this life, and carried out its destiny of unceasing food consumption in a distrait yet super-hungry manner, has proved to be tubercular, and hence as bacon can never repay me for all the care I lavished on him as pig.

Who can say after this list of events that a garden does not add incident and adventure to life. Those of my friends who during the war "looked on tempests and were never shaken" from their conviction that a gravel path is meant to be rolled, and a lawn to be mown, and herbaceous plants to be staked, and who allowed no vegetable to invade bed or border will have a poor time now. For their gardens are perfect, and theirs is the "dulness of complete felicity"; whereas my garden is all to make; all my mistakes are dead, and it will rise by stepping stones of those dead plants to higher things. The lawn, when the rest of the Savoys have hearted, will be sown with grass from which all Clover is excluded; none but the best perennials will find place in my borders, and those friends of mine will learn presently that patriotism pays—though whom, I will leave to the sympathetic reader to decide.

The strangest thing that I have seen in a garden for many a day is the behaviour this year of an Oak. Last year this tree, which is about 12 or 15 years old, retained its leaves until early spring, and stood in striking contrast with a companion Oak which was leafless before the turn of the year. This year I have been looking for a recurrence of the phenomenon, but to my surprise find that both trees have already lost their leaves. Now deciduousness is, I presume, an acquired habit, and our broad-leaved trees should, if they were born and bred, they and their forbears, in an equable climate, remain leafy all the year. If this is so, it looks as though this tree of mine, which last year kept its leaves, has not gradually but suddenly obeyed the behest of inherited habit or instinct, and given up all at once the ancient practice of keeping its leaves in favour of that of discarding them. The remarkable feature of the phenomenon lies in the suddenness of the change of habit, and is comparable with that said to be exhibited by certain deciduous trees when transported to regions of equable climate; from the first year, so it is said, these trees forsake their habit of deciduousness and become evergreen. *A. N.*

ON INCREASED FOOD PRODUCTION.

PREPARATION FOR ROOT CROPS.

THE preparation of the soil for root crops is more important than many gardeners realise. Early preparation is most advisable if good crops are to be obtained, since these crops need well-worked soil that is free from lumps. It will not be possible to prepare the ground before Christmas, but the work should be done as soon as possible afterwards, in order to allow plenty of time for the soil to settle.

Deep trenching is by far the most successful method of culture when shapely roots are required, and although it seems curious to advise trenching when labour is scarce, anything which tends to increased production should be most carefully considered. Demobilisation will ease the labour problem, and it is to be hoped that the Army will be disbanded sufficiently soon for labour to be available for trenching. In trenching ground for root crops very little manure should be dug into the soil, since it tends to make the roots fork; the little that is used should be buried two feet deep, for the roots will grow down and find the food where they require it. For both sandy and strong soils use pig and cow manures, and horse manure for heavy land. In addition to these natural manures, concentrated fertilisers, such as flue dust, wood ash, calcium cyanamide, and bone meal might be freely dug in during the trenching of the ground.

Provided that the work is done soon, there is no reason why the soil should not derive great benefit from being ridged and left as rough as possible. It is only when ridging is done at the end of February that no advantage is seen, and it is surprising how often one sees land ridged up too late for the frost to pulverise it successfully. Most of the severe weather comes after Christmas, so that if the work is carried out immediately the surface soil should become a fine tilth for the sowing of root crops after a couple of months of exposure.

The mistake that many gardeners make is to sow root crops too soon. Personally, I do not favour the sowing of Parsnips or Carrots before early in March, and Salsafy or Beetroot should certainly not be sown before April. The ground after ridging should be first levelled and then broken to obtain a fine surface. More rapid germination will take place if the drills are drawn early in the morning of a sunny day, and the seed sown in the drills after they have been warmed all day by the sunshine. Little points of this kind are more important than they seem, and result in greater success being obtained. *E. T. Ellis.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Hydrangeas and Fuchsias in Anglesea.—I recently spent a short holiday in Anglesea, and visited the place of my boyhood after an absence of thirty years. During the time of my absence I have often thought of the beautiful Hydrangeas and Fuchsias which grew there, and at times wondered whether the plants were really little things that appeared big to a small boy's mind. But not so. The Hydrangeas are still there, huge bushes, like Rhododendrons, covered with their trusses of pink and blue flowers. Plants with blue inflorescences predominate under trees or in woods, though these are not very plentiful on the island. I have never seen blue Hydrangeas growing naturally anywhere else. Fuchsias are also very fine; the plants make bushes 10 to 15 feet high, and are red with their little bells. Just before entering Holyhead station numbers of Fuchsias may be seen growing amongst the rocks, also amongst the rocks near the breakwater. The islanders do not appear to be very keen gardeners; one sees practically nothing in their gardens but Potatos. *Thos. E. Furnell, Quakers' Hall Nursery, Sevenoaks.*

Citrus trifoliata (syn. Aegle sepiaria) (see p. 157).—Citrus trifoliata has proved quite hardy in East Lothian, and, this season, I raised a batch of plants from home-saved seeds. I propose to use these plants for a hedge, which should be a very interesting one if the experiment is successful. Mr. Lynch refers to the crossing of C. trifoliata with the common Orange, and states that a hybrid known as the Citrange has been raised in France with the object of producing an Orange that would flourish in a climate that is too cold for the common Orange. I have no knowledge of this French hybrid, but it may interest Mr. Lynch to know that a British nurseryman is offering four new hardy Orange hybrids that have come from the United States, where they have succeeded in crossing C. trifoliata with some of the best kinds of Sweet Orange. I hope to have the opportunity of trying these hybrids next summer, although I doubt their value in our Scottish climate. Nevertheless, when one remembers that C. trifoliata is very late in starting into growth in the spring, that it ripens its fruit early, and becomes dormant fairly early in the fall of the year, one can imagine that if these characters are found in its hybrids, coupled with the sweet flesh of the edible varieties, it may then be possible to produce good Oranges out-of-doors in this country. At the International Conference on Hybridisation, held in London in 1899, under the auspices of the Royal Horticultural Society, Mr Herbert J. Webber, then in charge of the Plant Breeding Laboratory of the United States Department of Agriculture and Hybridisation, gave a most valuable paper upon the work of that department. The subject of Orange hybridisation constituted a large part of his lecture, and much interesting information was given in regard to C. trifoliata and hybrids therefrom. The difficulties of crossing C. trifoliata are dealt with, and various Citrus hybrids from it are described. These are raised from pollen of the Sweet Orange, the Tangerine (C. nobilis), and several others. A verbatim report of the lecture, with photographic illustrations of the various hybrids, will be found in the *Journal of the Royal Horti-*

cultural Society, April, 1900, Vol. XXIV. The object of crossing hardy Oranges was to secure a hardy race of Citrus fruits which would withstand the severe frosts that occur occasionally and cause serious damage in the Orange regions of the United States. *George M. Taylor, Portobello, Midlothian.*

The Loss of the Clematis in Gardens see pp. 165, 210, 220.—Messrs. Bunyard and Co., in referring to my article, wrote as if this serious problem did not exist, though there are many gardens in their own county that show it, as in Sussex, and also throughout our isles generally. Mr. E. A. Bunyard, who has given me the pleasure of a visit here, seemed pleased at what he saw, but may not have made a note of the Japanese Clematis, in good health, growing in the same place for over a quarter of a century. This was attained without any gain of soil or climate that other sites do not own, and every word said in my my article in your columns was duly weighed and based on actual trials for twenty years here. Messrs. Bunyard do not fix upon any word of mine as wrong, but wish it "withdrawn." Withdraw the result of many years' trials at my own cost, and now shown at Lyons as well as here? It cannot be done. As well ask Mr. Bean to withdraw his statements in *Trees and Shrubs* as to the bad results of grafting in various trees and shrubs. Of fragrant shrubs, many fine varieties of the Lilac have been destroyed for years by grafting on the Privet, an evil-smelling shrub in flower, the stock killing the Lilac and then taking its place in many suburban and town gardens. If anyone wishes to see an instance of this, let him go some summer evening to the Zoological Gardens, in Regent's Park, and if he escapes a headache he may know better what to do than plant Lilacs on Privet. Now, happily, growers both in Europe and America offer Lilacs on their natural roots, the only way to secure their health and endurance. Here, trees of forms of the Locust, Robinia, have been raised out for many years, and may be cited as to the benefit of grafting on trees. Struck by the beauty of the small-leaved form as a specimen, I planted standards in various aspects, and visitors rarely noticed the trees not owned on their age and vendure. After some years they began to look sickly, and one by one died, killed by the stock of the wild tree on which they were grafted. After much inquiry, I at last obtained a few small plants on their own roots; these grew slowly, but are now beautiful bushes, though planted in poor soil and an exposed aspect; these trees are as hardy and enduring as the type. The same thing happened with other varieties grafted on the wild form, in spite of much labour in removing vigorous suckers. Here, then, is another proof that trees of great garden value are lost by grafting. Few nurser men like to care for such trials, as many find to their cost, as it can do no good to the trade to send out trees which perish sooner or later. *W. Robinson, Gravetye, Sussex.*

SOCIETIES.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

DECEMBER 3.—The monthly meeting of this Society was held in the R.H.S. Hall on Monday, the 9th inst., Mr. Chas. H. Curtis presiding.

Two new members were elected. One member was allowed to withdraw interest amounting to £2 10s. 10d.; two members over the age of 70 years withdrew £55 18s. from their deposit accounts, and one member withdrew £22 18s. 10d. from his lapsed account.

The Army forms of the late Privates W. C. Croxford, E. Witten, E. Evesham, A. Gardiner, and R. W. Lane were received, and the sum of £18 0s. 1d. was passed for payment to their respective nominees. The death certificate was received of an old and esteemed member who had received over £240 in sick pay and still had a balance of nearly £100, which was passed for payment to his nominee. The sick pay for the month on the ordinary account amounted to £93 15s. 11d., State section to £54 6s. 8d., and maternity claims £4 10s. The trustees were empowered to invest a further sum of £500 in War Bonds. Mr. W. H. Divers was co-opted a member of the committee in the place of the late Mr. E. J. Allard.

CROPS AND STOCK ON THE HOME FARM.

THE 1919 ONION CROP.

ALTHOUGH the year 1918 was not favourable to the Onion crop in this district, mainly owing to drought during April, May and June, when only 2½ inches of rain fell, the result was better than was at one time anticipated. Wireworm was a source of trouble in newly ploughed grass land. During September, when 7½ inches of rain fell, the ripening of the bulbs was retarded, consequently among late planted bulbs there were many thick-necked specimens.

Those who intend to grow Onions in 1919 should prepare the soil early, so that if seed is to be sown in the open it may be got in early in March. No doubt the planting-out method has its advantages, but where labour is scarce I strongly advise outdoor sowing. When the plants in the boxes are ready to put out no delay should occur, as the seedlings become stunted and overgrown quickly and do not readily recover. The entire success is regulated by the rate at which growing proceeds.

Now is the time to apply twenty to thirty tons per acre of farmyard manure, and deeply plough it in. On the newly ploughed surface apply to the acre of lime-rubble slag, working it in by cross-ploughing, and surface as rough as possible to be pulverised by rain and frost. Under these conditions the soil is obtained early in the year and is not hindered. A crop giving from three to five tons per acre, at the Government prices of £24 and £30 per ton, cannot fail to be satisfactory. The ground for Onions avoid planting on a piece because of the constant [illegible] which Charlock grows freely in the seedling stage, as this pestiferous weed grows during the whole of the season, even as late as September, and robs the ripening bulbs of [illegible].

CULTIVATING ORCHARDS.

A [illegible] through what are known as [illegible] counties, or in districts [illegible] for market, will prove [illegible] the management of [illegible] Apple, Pear, and Damson, and [illegible] In regard to Pears, I am at a loss [illegible] more stocking Pears of attitude, for [illegible] As a rule this variety [illegible] and the fruits [illegible]

[illegible] is in the lack of [illegible] trees from moss and [illegible] the total absence of manuring.

[illegible] trees are dosed the [illegible] and plants are [illegible] also to take care [illegible] are planted. Grass [illegible] surface soil, right up [illegible]

[illegible] should be severely [illegible] weekly growth which [illegible] order to admit sun and [illegible] of the trees and induce new [illegible] to develop.

When pruning is finished the trees should be [illegible] with winter wash to rid the branches of [illegible].

I [illegible] in spraying the trees with [illegible] April, but as farmers [illegible] than too busy with spring sowing, [illegible] the trees do not always have the attention [illegible] I recommend a winter [illegible] will secure the same purpose, if the [illegible] given with the various proprietary [illegible] are properly carried out. When large trees show signs of waning vigour, and where it is not convenient to apply manures, copious supplies of liquid manure given any time during the winter or early spring months will provide an easy and effective method of stimulating growth and inducing fruitfulness. *E. Molyneux, Stanmore Farm, Bishop's Waltham.*

MUSTARD FOR SEED.

In consequence of the action taken by Agricultural Executive Committees, the acreage in England and Wales devoted to this crop has been reduced from 51,907 acres in 1916 to 9,999 acres in 1918. The crop is a profitable one to farmers, and it is also important to maintain the export trade, which is of considerable value. It has been decided therefore that an area of 20,000 acres should be allowed for the harvest of 1919, but that half of this area should be grown on land ploughed out of grass for the purpose. Mustard for seed is a very suitable first crop to be grown on newly ploughed grassland, and it is believed that many farmers would be prepared to break up grassland if they were allowed to use the land for growing Mustard for seed. The Board of Agriculture has made a general order prohibiting the growth of Mustard for seed except under the authority of a licence granted by Agricultural Executive Committees.

TRADE NOTES.

CHAMBER OF HORTICULTURE PROGRAMME.

THE Organising Committee of the Chamber of Horticulture has before it many suggestions for work, and proposes immediately to take steps to deal with the important questions of statistics, mechanical cultivators, imports and exports, and the treatment of diseases. These items, by the general consensus of opinion, call for prompt measures, and the Committee will put forward definite details in the near future.

Further subjects claiming the attention of the Chamber include soil sterilization, treatment of seeds (electrically and otherwise), fuel consumption, glass house construction, and cold storage, research work, and the serious question of transport difficulties, are down on the programme of the Committee for prompt treatment.

The Chamber is already in request by Government Departments for the purpose of advisory work, and, from the trade point of view, one of the problems to be met is that of competition among official bodies and traders. The setting up of special committees for arbitration and conciliation, the establishment of labour conferences, and the drawing up of a broad minded scheme for dealing with after war conditions, should tend to the establishment of closer relations between the various sections of the trade, which may be said to be the first and all-important aim for which the Chamber of Horticulture has been inaugurated.

NEW RETAIL PRICES FOR POTATOS.

THE Food Controller has decided, so far as is consistent with the undertakings given to growers, to relax the strictness of the Government control of Potatos. In order to give effect to this decision he will issue immediately an Order, called the Potato (Consolidation) Order (No. 2), 1918, which will so modify the existing Potato distribution scheme as to give greater freedom and latitude on sales by the growers and any dealings by wholesalers and retailers.

The following are the principal modifications:—

Growers will no longer require a licence to sell Potatos to retailers or consumers within their zone. The price at which they sell will, however, be the same, whoever is the purchaser, that is to say, it will be the grower's price fixed for the district, except that the grower may sell lots up to 1 cwt. direct to consumers at any price up to 1d. per lb.

The flat price for Potatos to retailers and consumers will be abolished, and wholesale dealers and retail dealers will sell on margins in the same way as last year. The wholesale dealers' commission will be averaged over four weekly periods, the first period beginning on December 16. During any such period the dealer's average profits must not exceed 4s. per ton for sales to other than wholesale dealers, and 10s. per ton for sales to retail dealers and consumers. The Potatos must in no case pass through the hands of more than two wholesale dealers, and any wholesale dealer who obtains Potatos through his Potato Control Committee may not resell them to another wholesale dealer.

The maximum retail price, as shown in the table printed below, will vary with the retailer's buying price, which for this purpose is reckoned as the sum of (a) the actual price paid for the Potatos by the retailer, excluding any sum paid as deposit on bags; and (b) any sum borne by the retail dealer in having Potatos carted to his shop. If he carts the Potatos in his own van he may include a reason

able sum, not exceeding 5s per ton, for this service.

The movement of ware Potatos from surplus to deficit zones will be controlled by the Ministry of Food as at present, but pig Potatos will be allowed to move freely from one zone to another. A grower may cart his ware Potatos to any place in any other zone within five miles of his farm; and ware Potatos, grown in Essex, Middlesex, Hertfordshire, and Bedford may be sent into London unless they are loaded at railway stations in other zones.

Wholesale dealers in deficit zones, who cannot obtain sufficient supplies of Potatos from within their own zone, will indent on their Potato Control Committee or Market Committee for supplies from other zones.

COUNTIES AFFECTED WITH BLIGHT.

In view of the abnormal development of blight in the Eastern counties and other special circumstances since growers' prices were fixed, these prices have been revised for the counties chiefly affected, and will be as follows during December for the King Edward and Langworthy group:—

Best land (Silt, Warp, Limestone, and Highland Clay).—Lincoln, Norfolk, Cambridge and Hunts, Soke of Peterborough, and Yorkshire, £7 in each case.

Other Land.—£6 5s. in Cambridge and Hunts; £6 10s. in the other counties named.

The prices for other varieties of Potatos will be 10s. a ton less than the above. The price for all varieties will be increased after the end of December by the amounts indicated in the Commission's report. The riddle for ware Potatos grown in Nottinghamshire will be reduced from 1½in. to 1¼in.

The following is the scale of maximum retail prices referred to above:—

Retailer's buying price per cwt. for Potatos delivered to his shop.	Highest authorised retail selling price over the counter. Rate per cwt. for lots of 1 cwt. or more.	Rate per stone for ½-stone lots or lots of 14 lb. or 7 lb. and more, but less than 1 cwt.	Rate per ½-stone lot or lot of 7 lb. and more, but less than 14 lb.	Rate per lb. for lots of less than 7 lb.
s. d.	s. d.	s. d.	s. d.	
Any price up to 6 3	7 2	1 0	0 6	
s. d.	s. d.			
Between 6 3 and 6 7	7 6	1 0½	} 0 6½	1d.
,, 6 7 ,, 6 11	7 10	1 1		
,, 6 11 ,, 7 2	8 1	1 1½	} 0 7	
,, 7 2 ,, 7 6	8 5	1 2		
,, 7 6 ,, 7 10	8 9	1 2½	} 0 7½	
,, 7 10 ,, 8 1	9 0	1 3		
,, 8 1 ,, 8 5	9 4	1 3½	} 0 8	1½d.
,, 8 5 ,, 8 8	9 7	1 4		
,, 8 8 ,, 9 2	9 11	1 4½	} 0 8½	
,, 9 0 ,, 9 4	10 3	1 5		
,, 9 4 ,, 9 8	10 7	1 5½	} 0 9	
,, 9 8 ,, 10 0	10 11	1 6		
,, 10 0 ,, 10 3	11 2	1 6½	} 0 9½	1½d.
,, 10 3 ,, 10 7	11 6	1 7		
,, 10 7 ,, 10 11	11 10	1 7½	} 0 10	
,, 10 11 ,, 11 2	12 1	1 8		
,, 11 2 ,, 11 6	12 5	1 8½	} 0 10½	
,, 11 6	—	12 9	1 9	

In cases where Potatos are sold with bags included, 6d. per cwt. must be deducted from the actual buying price in order to arrive at the buying price for the purposes of the schedule. For example, if Potatos are bought at the rate of 9s. 8d. per cwt., bags included, the selling price is determined by line 11 of the schedule, and not line 12.

SALES OF SEED POTATOS.

THE Seed Potatos Order (1918) which came into force on Monday last, requires a written declaration to be furnished by the vendor to the buyer on the sale of Potatos as or for "seed." The declaration must state the class and variety and dressing of the Potatos sold. In cases where seed Potatos are sold from crops immune from wart disease, they must be certified as reasonably free from rogues by the Board of Agriculture, or by the Board of Agriculture for Scotland. The declaration must also state the serial number of the relative certificate.

For the purpose of this Order the classes of Potatos sold as or for "seed" are:—

"Class I. (Scotch)," which includes only Potatos grown in Scotland.

"Class I. (Irish)," which includes only Potatos grown in Ireland.

"Class II. (once grown)," which includes only Potatos grown in England or Wales in respect of which documentary evidence can be produced showing that they were grown in the year 1918 from seed grown in Scotland or Ireland in the year 1917.

"Class III.," which includes all other Potatos.

The Order does not apply to Potatos sold in Ireland for planting in Ireland. It does not prescribe maximum prices to be paid to the grower, rates of commission on sales by merchants or retailers, or the size of riddle to be used in dressing Potatos for sale as or for "seed."

IMPORTATION OF JAPANESE LILY BULBS.

As the result of efforts commenced by the British Florists' Federation, directly after the signing of the armistice, the Board of Trade Department of Import Restriction granted permission for the importation of 10,000 cases of Lily bulbs from Japan on Monday, the 16th inst., and on the 17th inst. the Committee drew up a pro-rata allocation to those importers who received licences in 1916. This allocation was accepted by the Department of Import Restriction the same afternoon, and the importers were notified during the evening.

Obituary.

T. W. Pritchard. We regret to record the death of Mr. Thomas William Pritchard, for several years gardener to M. Hyslop Maxwell, Esq., The Grove, Dumfries. Mr. Pritchard, who was a son of the late Mr. Pritchard, gardener to the late Sir Emilius Laurie, Maxwelton House, gained experience at several good gardens, and was an able, all-round cultivator. He took a considerable interest in all horticultural movements, and frequently acted as a judge at local shows. He was of much assistance to allotment holders in the neighbourhood of Dumfries, by giving advice. Mr. Pritchard had been in poor health for a considerable time, and sanatorium and other treatment failed to restore his health, and he had to resign his appointment at The Grove a few months ago. He is survived by a widow and three young children. The funeral took place at Irongray Churchyard on the 12th inst.

THE WEATHER.

THE WEATHER IN SCOTLAND

November was a month of fog and rime, with a meagre amount of sunshine and a low rainfall. On thirteen nights the minimum thermometer in the screen fell below the freezing point, and read as low as 20° on the 23rd. Rain fell on thirteen days, yielding a total of 1·69 inch, the greatest fall of 0·61 inch being on the 1st. Of sunshine 54·7 hours were recorded, being an average of 1·8 hour per day, and a percentage of 22. There were thirteen sunless days. The mean barometric pressure was 29·93 inches, varying from a highest of 30·50 inches on the 12th to a lowest of 29·10 inches on the 2nd. The mean temperature for the month was 38·5°, with a mean range of 15° and an absolute range of 33°. On the 2nd, 10th, 3rd 16th, the highest maximum of 53° was recorded, and on the 23rd the lowest minimum of 20°, while the lowest maximum of 34° and the highest minimum of 42° were on the 22nd and 2nd respectively. The mean maximum temperature was 46°, and the mean minimum 31°. On the grass the mean minimum was 26°, with a lowest of 15° on the 23rd. There were twenty-four nights of ground frost. At 1 foot deep the soil temperature fell from 47° to 37°. For the month the air had the high relative humidity of 90 per cent. The prevailing winds were from the south-west. *James Mulloch, Training College Gardens, Kirkton of Mains, near Dundee.*

DEBATING SOCIETIES.

READING AND DISTRICT GARDENERS'.—"The Apple: Pruning and General Cultivation," was the subject arranged for the discussion at the meeting of the above Association on Monday, the 2nd inst., held in the Reception Club Room, Abbey Hall. Mr. H. C. Loader presided. Mr. T. J. Tubb (Bear Wood Gardens) opened the discussion on his first attendance to the meetings after receiving his discharge from the Army. Mr. Tubb explained his mode of summer and winter pruning of various types of trees, root pruning, and general management, such as the thinning, protecting and the picking of the fruit, watering and mulching. The lecturer staged a collection of 17 dishes of fruits of Apples, all in good condition and of excellent colour. Among the most noticeable were Cox's Orange Pippin, Golden Noble, Adams's Pearmain, Sandringham, Edward VII., Normandy Pippin, and Gascoyne Scarlet.

ANSWERS TO CORRESPONDENTS.

COMMERCIAL HORTICULTURE IN ENGLAND: *E. A. B.* The prospects of obtaining employment as manager of a commercial horticultural establishment in England would depend largely upon your knowledge of the trade in this country. If a knowledge of cultural and business methods in the United States can be added to experience here, there should be no great difficulty in obtaining employment. It is generally anticipated that horticulture will advance in the near future, and some people go so far as to predict a "boom." Your best plan will be to advertise your requirements and state what experience you possess.

CORRESPONDENCE SCHOOL OF HORTICULTURE: *J. C. R.* We have no knowledge of the Correspondence School referred to in your letter. Every young man should take advantage of any opportunity for improving his general education and acquiring a knowledge of those sciences which are directly concerned with the practice of horticulture. A list of books suitable for study, if you have a horticultural examination in view, can be obtained from the Royal Horticultural Society, Vincent Square, Westminster.

FROSTING SHRUBS: *G. H. S.* The following is a simple method of "frosting" shrubs: Put a sufficient quantity of thin, clear starch into a pail, into which dip the evergreen branches; then apply "Jack Frost" powder while the foliage is wet, and stand the branches in a dry, warm place. The "frosting" quickly dries, and the branches are then ready for use. The powder can be obtained at most fancy or toy shops.

LOGANBERRY NOT SATISFACTORY: *Sherwood.* You are not alone in your experience of the fruits of the Loganberry being defective, for it is a common occurrence for them to be infested with grubs, causing the flesh to be hard and unpalatable. The Himalaya Berry is one of the best of the numerous fruiting Rubi, and you might try this Bramble as a substitute for the Loganberry.

MANGOLD WURZEL: *C. H. C.* The word Mangold is certainly of Teutonic origin, but it would be impossible, even were it desirable, to expunge all such words from the English language. The spelling "Mangel" is simply a corruption of "Mangold," due to careless pronunciation. Certainly the further corruption of the spelling to "Mangle" would lead to some strange confusions, as you suggest.

MARKET GRADES OF TOMATOS: *C. P. B.* Tomatos are sold in the market in baskets known as strikes; each strike holds 12 lbs. A tally is five dozen. The highest grade Tomatos are packed with pink and white paper; for the smaller, "best" samples, pink paper is used; blue paper for ordinary and seconds. In usual practice there are these four grades.

NAMES OF PLANTS: *H. E. S.* Veronica Andersonii: one of the handsome garden forms raised on the Continent.—*G. E.* Fruits of Datura Stramonium—the Thorn Apple.—*W. M. M. D.* 1, Cypripedium insigne; 2, C. Boxallii, 3 and 4, varieties of Maxillaria porphyrostele; 5 and 6, forms of Calanthe Veitchii.—*G. Figgis.* Vaccinium corymbosum.—*T. H.* 1, Santolina incana; 2, Gypsophila prostrata; 3, Helianthemum sp.; 4, Clematis apiifolia; 5, Juniperus chinensis var.; 6, Azara microphylla; 7, Escallonia macrantha; 8, Jasminum revolutum; 9, Clematis paniculata; 10, Skimmia japonica; 11, Cassinia fulvida; 12, Ceanothus americanus var.

RHUBARB: *Sherwood.* The Sutton variety is one of the finest of all Rhubarbs. We find it gives stalks as early as the majority of varieties, and is, in our opinion, superior to Victoria.

THE ASPARAGUS PEA: *J. C.* Seeds of the Asparagus Pea (Lotus Tetragonolobus) are probably not obtainable in this country at the present time. The demand for the plant is very small in this country and it is not, we believe, ever grown here for seed purposes.

NOTES FROM KEW.—XII.*

At this peace-time Christmas one should write about Mistletoe and crackers with mottos, and laurels for wreaths for the victorious. But the editorial order is for notes about some of the nice things in flowers at Christmas, berried shrubs and such-like garden decorations. There are not many this year, at any rate, not at Kew. Hollies, Pyracantha and Pernettya are nearly stripped of their berries already, Kew being a bird sanctuary, and the birds being unreasonably fructivorous. There would be nice Roses were it not for the rain and semi-darkness experienced this sloppy month. Soft weather has brought into flower the Witch Hazels and Rhododendron Nobleanum and R. dahuricum. Christmas Roses are in bloom, too, and Iris stylosa. The sun must shine now and then if we are to have flowers of any kind. In the houses there are fewer plants in bloom than there ought to be. Fog has withered up some things, and the absence of sunlight has caused many flowers to rot in the bud. Gardening is a precarious occupation. It is war most of the time.

The most striking of the comparatively few Orchids in flower is Schomburgkia splendida, a well-named species which flowered for the first time in December last year. The plant was presented to Kew in 1900 by Mr. Elwes, with whom it had failed to flower. According to Mr. Rolfe, who identified it, specimens were first collected by André on the Rio Dagua in 1876, and later by Lehmann on the Rio Esmita, Colombia. The species is the largest of the dozen or so known, the flower-spikes being 5½ feet high with about a dozen flowers in a cluster at the top, each flower measuring 4 inches across; the sepals and petals are strap-shaped, very wavy, and coloured glossy brown-purple; the lip and column are bright rose-purple, except for a small white patch on the front lobe; pedicels 4 inches long, twisted, and white. Like S. crispa, S. undulata, S. marginata, and the well-known S. Tibicinis, the plant is straggling and awkward in habit, and the scape is too long for the ordinary plant house; but seen at close quarters the flowers are strikingly handsome, though on the dusky side. The genius might very well be combined with Laelia, L. superbiens, for example, being as like to the long, loose-growing Schomburgkias as one Pea is to another.

The white variety of Cattleya Maggie Raphael is a superb hybrid. It blooms in mid-winter, and its large, shapely, white flowers, with red-stained lip, are greatly admired. The plant is good-natured, too, growing freely and flowering strongly, the Kew example having four good blooms on one scape. I may take this opportunity to record the great gift of Cattleyas and other Orchids made to Kew by Sir George Holford in 1913. A house had to be built for their accommodation, and the plants generally have maintained the reputation of their former home, the famous garden at Tetbury, by growing and flowering so satisfactorily that there has always been an attractive display, particularly of Cattleyas, Laelias and Cymbidiums. If any reader happens to have tropical Orchids, such as Vandes, Aerides, Saccolabiums and Dendrobiums which have outlived their welcome there is room for them at Kew, where they would meet with proper appreciation. The collection has felt the effects of war conditions in respect of such Orchids. Cypripediums are well represented.

The experiment with sponge trimmings as a substitute for peat fibre for Orchids has not proved the success that I anticipated. With the exception of Cypripediums, which appear to revel in sponge, the roots do not like it. I am unable to account for this fact. Possibly if the experiment had been made with seedling Orchids the result would have been better. Plants that had lived in peat for years may not be able to find their requirements in sponge, or it may contain something that most Orchids dislike. There can be little doubt that a mixture of air and water is all the nourishment epiphytic Orchids naturally get. As a rule the plants go wrong when the compost about their roots breaks down and becomes what is known as sour.

Whilst so many good greenhouse plants have been allowed to drop out of cultivation, hard-wooded plants in particular, the Acacias are still in favour. There are few better shrubs than A. platyptera, and its lemon-coloured variety, alata, for decorating a conservatory in mid-winter, and there is not one that surpasses A. Baileyana when grown as a pillar ornament. Its grey-green leaves are always pleasing, and when the long, leafy shoots are laden with elegant racemes of golden yellow-fragrant flowers it is loveliness in excelsis. Grown as a loose shrub and pruned heavily every year after the flowers fade, this Acacia stands out conspicuously among the many species that are represented in the Kew Temperate House. I have seen trusses of the flower-laden shoots of it offered for sale in winter in the London flower shops, and I am told that in the South of France A. Baileyana is supplanting A. dealbata for this purpose. Has the former been tried in South Cornwall? It is said to be at least as hardy as A. dealbata, of which there are good-sized trees in gardens Falmouth way. Here is a list of the most decorative plants in flower in the houses in Christmas week: Acacia leprosa, A. urophylla, A. linearis, A. pulchella, A. Baileyana, A. alata, A. platyptera, A. dealbata; Begonias, socotrana, Gloire de Lorraine, Glory of Cincinnati, Mrs. Peterson, Gloire de Sceaux, and semperflorens, gigantea; Buddleia officinalis, B. asiatica, Centropogon, Lucyanus, Cestrums, Calceolaria Burbidgei, Carnations, Cyclamens, Camellias, Chorizemas, Crowea saligna, Calanthes, Cypripediums, Cattleyas, Daphne odora, Diospyros Kaki (fruits), Eucharis grandiflora, Euphorbia fulgens, Epacris, Eupatoriums, Heeria rosea, Hymenocallis speciosa, Impatiens Sultanii, I. Holstii, I. Oliveri, Ipomœa Briggsii, Jacobinia chrysostephana, Lindenbergia grandiflora, Laelias, Luculia gratissima, L. Pinceana, Orange (flowers and fruits), Peristrophe speciosa, Primula obconica, Poinsettia, Protea pulchella, Richardias, Reinwardtias, Strobilanthes isophyllus, Strelitzia kewensis, Sparmannia africana, and Tibouchina semidecandra. Not an impressive list. May we blame the weather or the Germans, or both, that it is not better?

The two Buddleias mentioned in the list are greenhouse shrubs which bear trusses of small, grey-white, tubular, very fragrant flowers, even small plants in 5-inch pots flowering profusely.

Begonia socotrana, which made its first appearance at Kew in 1881 and has never since lost favour, is represented by a group of well-grown examples now in full flower. The plant is worth growing for its foliage alone: orbicular, peltate, with a recurved, toothed margin, rich green and from 6 inches to 8 inches in diameter, the leaves are of the kind that never fails to arrest attention; and the bright rose-pink flowers, always produced in mid-winter, are a delight unless fog spoils them, as it sometimes does. As the parent of a large family of winter-flowering Begonias, including Gloire de Lorraine and the grand hybrids raised by Mr. John Heal, the best of which are now making a great show in No. 4 greenhouse, the Socotran species has a strong claim to the gardener's affection. It requires a dry rest after flowering till June, when the plants should be shaken out, repotted, and started again in a warm house.

The Gentians deserve to rank even higher than they do in horticulture. There does not appear to be a Gentian specialist, yet there is ample material and interest in the genus to make it worth while. China has lately added several first-rate species, exactly what the alpine gardener wants, as they grow freely, form the right kind of tufts, and are as floriferous as they are charming. The photograph reproduced in fig. 103 was intended to accompany last month's

* Previous articles appeared in the issues of January 19, February 9, March 9, April 6, May 18, June 8, July 6, August 10, September 21, November 2, and December 7.

notes. It represents one of the latest introductions from China, and as it was in the Kew Rock Garden on mid November. It is quite hardy, and the flowers, nearly the size of the Gentiana acaulis are a rich, clear blue. I think this must be the same Gentian which Mr. Perry showed on October 12, 1915, and obtained the R.H.S. Award of Merit for, under the name of G. ornata, but the true species of that name is Himalayan, and is paler in colour, as shown in *Bot. Mag.*, t. 3,140; the name of the Chinese species illustrated in fig. 103 is G. sino-ornata. I am not certain whether the plant called G. Veitchii, or Veitchiorum, is the same or a form of it. There can be no doubt, however, as to its worthiness, and in a fairly moist soil, not too much exposed to direct sunshine, it is as happy as the best natured of the older Gentians. G. Freymana, G. Lagodechiana, G. Kurroo, G. Przewalski (a shocking name for a lovely plant) and G. septemfida are others that only need to be seen to inspire the wish to possess. I do not know enough about the latest comer, G. Farreri, but from accounts of it by Mr. Farrer and others it is a champion. Another of Mr. Farrer's finds in Tibet is G. hexaphylla, which, in his delightful book, "On the Eaves of the World," he figures and describes as "one of the most lavishly lovely of its race." The description given in the same book of G. Farreri is worth quoting here. "The vivid and violet gloxy of my own Gentian of the Da Tung, by far the most dazzlingly beautiful I have ever seen, relegating G. verna, G. excisa and G. bavarica to mere dowdiness. The shrill and incandescent azure of G. Farreri's great trumpets, visible a quarter of a mile away in the grass, like stars of burning sky, or the green lights fallen from a rocket." The flowers open in early September on the alpine heights of Da Tung within but a few weeks of final winter. This is surely enough to make us all Gentianites."

Mention should have been made in July of the interesting little hardy Japanese Gesneriad, Conandron ramondioides (fig. 104), which for the last twenty years or so has been grown on the rockery at Kew, where it is as happy as its cousin, Ramondia pyrenaica. There is also an affinity with Streptocarpus suggested by the habit and foliage of the plant, though there is none in the flowers, which in the Conandron are star shaped, ivory white, and about an inch across. A shaded crevice in a rock wall is the best position for the plant, and it likes a peaty, moist soil. Its home is in the mountains of Japan, whence it was introduced by Messrs. Veitch and described by Dr. Masters in *Gard. Chron.* in 1879.

FIG. 104.—CONANDRON RAMONDIOIDES: FLOWERS IVORY WHITE.

Kewites will no doubt be interested to learn that the wages of gardeners, both male and female, are now 24s., plus 23s. war bonus, also that all Kew employees who joined His Majesty's Forces are entitled, on being discharged, to return to their posts in the gardens. W. W.

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENCER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Mushrooms.—A steady temperature of 50° to 55° should be maintained in the Mushroom house without the aid of fire heat if possible. This cannot always be done, but in no case should an excessive amount of fire heat be used. A dry atmosphere must be guarded against by damping the floors and walls. Continue to collect manure for the making of new beds, and place it in a dry, open shed where it can be turned frequently.

Carrots.—A sowing of Early Horn Carrots should be made before the turn of the year in frame pits if they are available. Make up a bed of litter and leaves as previously recommended, about 4 feet in depth; tread the materials firm, and cover the bed with soil about 4 inches in depth. Sow the seeds thinly and dust the soil with wood ash as a check to slugs. Little or no water will be necessary until lighter days, when the pits or houses may be ventilated and the syringe used sparingly on sunny days.

General Remarks.—At the end of what, on the whole, has been a good year for vegetables, many kinds are still plentiful and good. Scarlet Runners, Dwarf Beans, and Peas continued in full bearing to a very late period. Autumn Giant and other Cauliflowers have been extra good. Brussels Sprouts, Broccoli, Leeks, and Celery look well, and promise a full supply for some time to come. The present is a suitable time to compare notes and select the various kinds of vegetables for next season's crops. It is difficult to make selections to suit all purposes; those in charge know best the particular requirements of the establishment. Seeds should always be ordered in good time. Where early forcing is contemplated, preparations should be made by forming hot-beds and sowing small quantities of such seeds as Lettuce, to have young plants in readiness when needed in the spring. Push forward all kinds of work and any alterations which are in hand or contemplated, as pressure of work increases daily after the turn of the year. Continue to lift and expose roots of Rhubarb and Seakale, placing them in heat as required. Small quantities only should be forced at one time to maintain fresh and

constant supplies. Much other work can be done during bad weather, including the preparation of stakes and labels and turning heaps of old vegetable refuse. It is surprising at what a rate so-called rubbish accumulates in gardens, but this may be turned to good account in various ways, and made to enrich the soil. Its effects are often more permanent, and especially in heavy ground than when the soil is dressed with animal manure.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

Laelia.—Plants of Laelia autumnalis, L. albida and L. purpurata should be rested for a period after they have flowered; only sufficient water should be given the roots to keep the pseudo-bulbs fresh and plump. The early-flowering varieties of Laelia anceps are opening their flower-buds, and they will be followed in bloom by the white forms. By judicious management the blooming period of this useful species may be extended for several weeks. Laelia pumila and its many varieties will soon have passed the flowering stage, and, as soon as roots develop from the new pseudo-bulbs, any necessary repotting or top-dressing may be attended to. Shallow Orchid pans without side holes form the most suitable receptacles, and they should be fitted with wire handles. The plants thrive when suspended from the roof-rafters of the intermediate house. In repotting, the pots should be filled to one-half their depth with drainage materials, and the compost should consist of a mixture of chopped Al fibre and Sphagnum moss, with a quantity of half-decayed Oak leaves and crushed crocks added. Watering should be done very carefully, very little water will be needed until after the young roots have grown to the pots' sides, whilst during the resting period only sufficient moisture should be afforded to keep the pseudo-bulbs fresh and plump.

Vanda. Vanda Amesiana and V. Watsoniana are in bloom and if the roots are kept moderately dry the flowers will last for a long time in good condition. When the flowering season is over, just sufficient water should be given to prevent the roots from shrivelling, as the plants need a short period of rest. V. Kimballiana has passed out of flower, and should be rested next; the roots again become active when moisture may be afforded in increasing quantities. Plants of V. teres and V. Hookeriana having completed their season's growth should be given a lot of rest, affording them only sufficient water at the roots to prevent their terete leaves from shrivelling. These Orchids should be grown in the lightest position in a house having an intermediate temperature. V. coerulea should be rested for a period after passing out of flower in similar conditions to those recommended for the other species.

Cattleya. Plants of Cattleya Warneri which are growing actively should be stored in the warmest part of the Cattleya house in a light position, and be sufficiently watered at the roots to keep the compost moist until the flowers have opened. The work of repotting should be done immediately after the flowers have faded when new roots usually develop from the bases of the young pseudo-bulbs. The various forms of Cat. Trianae and C. Percivaliana are sending up flower spikes. The plants should be given an increased supply of moisture at the roots, and grow near the roof glass in a light, warm position.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

Flavour of Fruits. I have been gratified during the past season to receive many enquiries with respect to the flavour of out-door fruits. This is a good sign, for if quality were considered before large size more satisfaction would result to the gardeners. The highest coloured Apples are not necessarily the best flavoured.

Fruit for Preserving. Fruit should not, even when plentiful, be used for preserving in a haphazard manner. There is room yet for improvements in the combination of certain fruits for preserving besides the universal mixture of Raspberries and Red Currants. I recently sampled some Blackberry and Rhubarb jam; it was excellent. When more bottles are available there will be a great increase in fruit bottling. The samples of fruit preserves that have been staged at the R.H.S. meetings from time to time have created considerable interest.

The Demand for Trees. There is a very unusual demand on the nurseryman for fruit trees of all kinds, and many planters will have to wait longer than usual before their orders are executed. Whilst waiting for the trees, follow the advice already given to have everything in readiness for planting immediately they arrive.

A Retrospect.—At the close of another year's work in the hardy fruit garden, a few observations on successes and failures may be appropriate. I only remember one similar year of soil general failure here, and that was nearly forty years ago—on that occasion the crops were, so far as Apples are concerned, even worse than in 1916 and the future followed, if I remember rightly, a very severe winter. The shortage in the hardy fruit crops has been attributed to spring frosts and the unfavourable weather of April, but I am inclined to attribute it in some degree to the phenomenally heavy crops in 1917. Insects have been more troublesome during 1918 than for some years past. Aphis on Apple was especially troublesome, but our trees escaped serious injury from caterpillars. Aphides were troublesome early in the spring, but not so much later, whilst red spider was not much in evidence. Mildew did not cause any serious harm; in fact, some plants, including Roses, were remarkably free of this disease. In the coming season it behoves growers to use all measures possible against these common enemies of the fruit cultivator. Trees have made good growth during the past summer and autumn, and from observations made in several gardens there is a promise of plenty of flowers next spring. Both Cherries and Pears look unusually promising in many gardens.

FRUITS UNDER GLASS.

By W. J. GRISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

Planting and Potting Materials. A supply of fresh fibrous turf should be cut and stacked before frost and rains saturate the ground. A rich, clayey loam is the most suitable soil for fruits. In some districts turf soon loses its fibre and in such cases it should be used in a fresh state with plenty of grit, mortar rubble or broken bricks added to keep it open for the free passage of water. Soot lightly scattered over the turves when building the stack, adds to the quality of the compost. Cut grass from shrubbery or other walks will afford the necessary loam from rabbits. Wood ash from the garden fire forms the only available supply of potash at the present time; store the ashes in a dry place as potash is very soluble and soon washed out by rains. A stock of old mortar or lime, rubble, soot, and bone-meal or charcoal should be kept under cover, the soot and charcoal in tubs or boxes. At Keele we have open sheds in which to store horse manure and old Mushroom bed material; it is important to have these materials in a friable condition when required for various composts.

Early Vines. Early Vines are required to produce very early Grapes they should be stood on a bed of fermenting material for a few weeks. Keep the canes tied to the stakes for the present, and with slight syringings with tepid water the buds will break evenly on every part of the rod with little or no fire heat. The canes should then be tied to the wires. In the meantime a minimum temperature of 50° at night is sufficient warmth. When starting early permanent Vines, the requisite temperature may be maintained for a few weeks by placing a bed of fermenting material over the borders. A night temperature of 50° to 55° with a rise of 10° during the day, will be suitable for the first month of forcing. If the Vines are hurried in growth the buds will break irregularly. Maintain a moist atmosphere to assist the Vines into growth, freely syringing the house twice daily according to the weather with tepid water. Keep the evaporating troughs filled with water.

Late Vines. Directly the leaves have fallen from late Vines the laterals should be pruned. Always prune to a strong, plump bud, and, as a precaution against bleeding, paint the cut surface with styptic. During the next few weeks advantage should be taken of bad weather to thoroughly cleanse the house, and top-dress the borders with fresh loam, removing, in the first instance, a few inches of the surface soil. Soak the border with clear water, and ventilate the house to its fullest extent day and night.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Gloxinia. Shake the soil from some of the best matured Gloxinia tubers and place them in boxes of finely sifted leaf-mould. Let them develop in a warm house, and when top growth and roots become active place them in 5-inch or 6-inch pots filled with a compost made of rich fibrous loam, peat, leaf-mould, and coarse sand. After a few days water the soil thoroughly, and subsequently afford water with great care, and continue this treatment until the pots are filled with roots. The plants should be grown in a position near the roof glass in a warm house until they begin to develop flowers, when a cooler and drier atmosphere is more suitable. Fresh batches may be started into growth at intervals according to requirements.

Streptocarpus. This plant is very subject to attacks of mealy bug, and when the pest is established on the leaves it is very hard to exterminate. The plants should be examined at regular intervals for the purpose of destroying any insects which may be present. If plants are required to flower early a few may be placed in a warm house. Remove a little of the surface soil to allow room for a top dressing of fresh compost. A mixture of fibrous loam, peat, leaf-mould, manure from a spent Mushroom-bed and sand forms an excellent rooting medium for Streptocarpus. Young plants in 5-inch pots may be shifted into larger receptacles when they are sufficiently well rooted for transference.

Allamanda. Old established plants of Allamanda may be pruned. If they have filled their allotted space the shoots may be cut hard back to two buds. The plants are in need of a rest, therefore the roots should be kept dry during the winter. Specimens growing in pots may be pruned in a similar manner, and laid on their sides beneath a stage in a cool house until the spring.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

Reconstruction in the Flower Garden.—All will be thinking of re-establishing flower gardening on something like its former basis. One good result here was the tarring of a number of beds and borders four years ago, none of which will probably ever be restored, the general effect being much better without them. One cannot doubt that throughout the country flowers have been employed in the past in gardens much too profusely. That is apart altogether from the question of labour, and consequent expense. There had been for years a lack of restraint in the employment of flowers. It is true that never previously had flowers, as regards colours, been used so artistically, but it is also true that much artistic value was dissipated by the profuseness with which flowers were used. And it was in small places where the sense of proportion was most often lacking in this respect. I have been able by the aid of female labour to keep lawns mown as formerly, or, rather, more frequently, to make it easier for the girls. But gardeners here and there have permitted lawns to go wild, or ploughed them for Potato growing. In the first case there will be some trouble in restoring them to their former condition. It is true that previous to the era of lawn mowers it was not unusual to take a crop of hay annually off lawns, the rest of the season being occupied in keeping down the grass by scythe mowing. Under present day circumstances a very early mowing of the grass should be made, and very frequent re-mowing thereafter until hot weather relieves the pressure.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER, 41, Wellington Street, Covent Garden, W.C.**

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38.3°.

Fruits for Small Gardens.

Mr. Bunyard's lecture* on increasing the home fruit supply deserves to be studied by all owners of small gardens. His statement that much might be done to extend the period during which fruit is available is undoubtedly correct, and the wisdom of planting for succession recognised by all good gardeners deserves to be put into practice much more generally than is the case in the small garden of the present day.

For example, in spite of the excellence of their fruits, how rarely are autumn fruiting Raspberries planted in small private gardens? Yet the good varieties are prolific, and yield into October. These fruits are indeed particularly suited to private gardens, for they are not likely, owing to their lack of keeping quality, to become grown on a large scale for market—at all events in any but the drier parts of this country. By the simple device of "tipping" Raspberries in spring, so that the canes are left at varying heights—from 2 feet to 4 feet—the season of fruiting will be extended, for the shorter canes will fruit later. Similarly, the period of Strawberries might be extended by the planting of autumn fruiting varieties. It is doubtful—as Mr. Bunyard points out—whether the owners of small gardens have yet taken full advantage of the great improvement in the Gooseberry, the best varieties of which are among the most delicious of dessert fruit. Here, too, an extended season may be provided by the judicious planting of late varieties.

Mr. Bunyard's golden rule for fruit gathering deserves to be committed to memory. Gather late varieties of Apple and Pear late, and early varieties early—that is, whilst they are still firmly attached to the tree.

The "going soft" at the core, which so often befalls Pears, is frequently due to the fact that the fruit was gathered late.

Needless to say—in the rule observed—late keeping fruit should not be gathered until it is about to fall from the tree.

Mr. Bunyard's advice on keeping fruit will be welcome to those who do not possess a fruit room—wrap Apples or Pears in paper, put them in a box, close the lid, and put the box in a cupboard or shed. The shed need not even be frost-proof.

Those whose gardens are ever troubled with wasps should act on Mr. Bunyard's remark that cooking Plums may be stored for some time when gathered unripe.

The importance of the proper soil-treatment of fruit trees is often overlooked, and, next to the lawn, the fruit quarter is often the most starved part of the garden. Lime is often deficient, and, if so, must be supplied either in the form of lime or else chalk or lime refuse from the manufacture of acetylene gas. For starved, unthrifty trees nitrogenous manures should be used, but excess of such manures must be avoided, as it will result in increased growth and decreased fruit production.

Without a supply of phosphates in the soil fruit crops will be small, and care must be taken to supply any deficiency by a dressing of superphosphate or of basic slag. Mr. Bunyard advocates the extended planting of fruit trees in small gardens. Instead of the Bitter Almond, ubiquitous, lovely, but evanescent in its loveliness, suitable fruit trees should be planted in suburban gardens. Large growing trees, Limes and Beeches and the like, should give place in the small garden to Apples and Pears, and the shrubbery, with its dull monotony of Laurels, should be diversified by the introduction here and there of these fruits. What Canada has done in the extension of fruit growing in the colder parts of the Dominion should be attempted here, and in the north the cold-resisting and late-flowering varieties sidered good value.

With the national programme of housing an unique opportunity will arise for illustrating the possibilities of fruit growing in small gardens, and it is to be hoped that this opportunity will not be lost sight of; in any case, those who have such gardens should read Mr. Bunyard's instructive article with attention, and put into practice the excellent advice which he gives.

* *Journal of R.H.S.*, May, 1918

"Botanical Magazine." — *The Botanical Magazine* for July to December, 1918 (Nos. 1,577 to 1,582 of the work) comprises descriptions and illustrations of the following plants: Sophora japonica, Ramondia serbica, Gongora latisepala, Rhododendron argyrophyllum, var. leiandrum, Govenia tingens, Linum elegans, Alnus firma var. Yasha, Stewartia serrata, Polystachya Pobeguinii, Hypericum laeve forma rubra, Scabiosa Hookeri, Rhododendron orbiculare, Mesembryanthemum fulviceps, M. Elishae, Primula sinopurpurea, Stewartia sinensis, Cereus Tunilla, Odontoglossum praevisum, Berberis Beaniana, Diascia Aliciae, Mesembryanthemum edule, Rhododendron oreotrephes, and Bulbophyllum Hamelinii. Ramondia serbica is a pretty plant for the rock garden, bearing a close general resemblance to R. pyrenaica. Gongora latisepala was presented to Kew as an unnamed specimen in 1914 by the late Lady LAWRENCE. It has brilliant orange-coloured flowers, covered with reddish-brown spots. Linum elegans well deserves its name—it is a native of Greece, and may not prove quite hardy in this country. Stewartia serrata is hardy at Leonardslee, from whence the flowering spray which figures in the illustration was gathered. It is a very striking shrub, bearing pale yellow flowers with crimson blotches on the reverse of the petals. Hypericum laeve forma rubra is a native of the East, and was discovered near Diarbekir in 1841. It is thought by some authorities that the colour of the red form may be attributable to the ferruginous nature of the loam in which it grows. Rhododendron orbiculare, a native of Western Szechuan, bears flowers of a brilliant rosy carmine. The species is fairly hardy, especially in the damp, mild climate of the West of England. Primula sinopurpurea was raised at Kew from seed collected in Yunnan by Mr. G. FORREST. It was described and illustrated in the *Gardeners' Chronicle*, 1917, vol. lxii., p. 241. Stewartia sinensis is also a native of China, namely, of Western Hupeh. The flowers are white, with brilliant yellow anthers. Mesembryanthemum edule is perhaps the finest of the genus. It is a native of South Africa, and in most parts of Britain requires the protection of a greenhouse during the winter. Bulbophyllum Hamelinii flowered in 1902 at the Glasnevin Botanic Garden. It is a native of Madagascar, and thrives best in a tropical house, in a suspended basket of peat and Sphagnum.

Trials at Wisley in 1919.—The Royal Horticultural Society will carry out trials of Dwarf French Beans, Cauliflowers, Lettuces, Parsleys, Early Potatos, Turnips, and Swedes in their Gardens at Wisley, Ripley, Surrey, during 1919. Seeds, etc., for trial should reach the Director of the Gardens not later than January 31, 1919.

Army Stable Manure.—Farmers in Surrey, Sussex and Hampshire who are near enough to Aldershot can obtain manure from the Eelmoor Dump at 5s. per ton. Analyses of Army stable manure show that it is very satisfactory in composition, and at this price must be considered good value.

Royal Horticultural Society War Relief Fund.—A meeting of the War Horticultural Relief Fund was held at the Mansion House on Wednesday, December 18, 1918, at 3.30 p.m., under the presidency of the Lord Mayor of London, Sir HORACE MARSHALL, who was accompanied by the Lady MAYORESS. On the platform were Field-Marshal Lord GRENFELL, the president of the Royal Horticultural Society, and also of the Fund; Lady NORTHCOTE, vice-president of the Fund; Mr. CARL HENTSCHEL, one of the joint secretaries; the Rev. W. WILKS, Sir HARRY J. VEITCH (treasurer), Sir CHARLES WAKEFIELD, Master of the Gardeners' Company, Mr. JAMES W. LOWTHER, the Speaker of the House of Commons, and many others. The Lord Mayor, in the course of his speech of welcome to the audience, read a letter from Mr. A. J. BALFOUR regretting inability to be present, and conveying his best wishes for the success of the Fund. A letter from Lord BURNHAM was also read, to the same effect. Mr. HENTSCHEL then read a letter sent by Monsieur POINCARÉ, the President of the French Republic, to Monsieur CAMBON, the French Ambassador in London, expressing his gratitude to the promoters of the Fund, and one in a similar vein from the Serbian Minister. Sir HARRY J. VEITCH, as treasurer, then gave a few details as to the money which had been received, and the work which it was hoped to do in restoring the devastated lands in France, Belgium, and Serbia, and especially in providing seeds and plants. Mr. JAMES LOWTHER, who described himself as a humble follower of the horticultural craft, gave a graphic description of the devastated districts, over part of which he had travelled, and laid emphasis on the importance of restoring as quickly as possible the fields and gardens which

were so necessary to the life of the people. Sir CHARLES WAKEFIELD dwelt on the permanent nature of the work which it was proposed to do, which should, in his opinion, form a link to bind in friendly comradeship all the peoples of the Allied countries. Lord GRENFELL then proposed a vote of thanks to the Lord Mayor for allowing the use of the Mansion House for the meeting, and for his kindness in presiding. He reminded those present of the historical year 1815, when the victorious allied generals, WELLINGTON and BLUCHER, were fêted in that very hall. The year 1919 was likely to be no less famous in history. The motion was seconded in a few cordial words by Lady NORTHCOTE, on behalf of the women's section of the Fund, and the vote was carried unanimously, the Lord Mayor replying in a very short speech. Before and after the meeting several songs were sung by a Serbian boys' choir.

Apple Monarch.—The new, late-keeping Apple Monarch (see fig. 105), introduced by Messrs. W. SEABROOK AND SONS, is the result of a cross between the varieties Peasgood's Nonsuch and Dumelow's Seedling. The fruits are large—often very large—and handsome in form and colour. The skin is pale green, with a bright red flush which, with the rounded outline of the fruit, at once suggests Peasgood's Nonsuch as one parent, while the open eye, set in a puckered basin, the keeping quality, and brisk flavour, are suggestive of Dumelow's Seedling (Wellington). It should be stated, however, that Monarch is less acid than Dumelow's Seedling and less sugar is needed to make the fruit palatable when it is cooked. The tree has a rather spreading habit, and on the Paradise stock makes a specimen from 12 feet to 15 feet high. There is ample room for a late-keeping and attractive Apple such as Monarch, which is in excellent condition from October to April, and is of fair dessert quality after February.

Contributions to our Knowledge of the Vegetation and Flora of the Islands, excluding Madagascar, of the Western Indian Ocean.—Dr. W. BOTTING HEMSLEY has contributed to *Nature* an article on the Palms of the Seychelles and the Mascarenes—Mauritius, Bourbon and Rodriguez—the new facts, relating to the Seychelles genera and species, being mainly from notes supplied by Mr. P. R. DUPONT, curator of the Botanic Station at Mahe. Since the publication of the veteran Mr. J. G. BAKER'S *Flora* forty years ago, no addition has been made to the number of species of Palms known to inhabit this insular region, noted for its peculiar endemic types of the Palmae. But all those recorded by BAKER still exist in more or less abundance. Altogether there are fifteen species belonging to nine genera, and these genera are, so far as present knowledge goes, all restricted to the islands in question. All are, or have been, in cultivation in this country, but, being mostly trees of large dimensions, they need spacious hothouses for their development. The Seychelles species are six in number and peculiar to the group. They are: Lodoicea sechellarum, Acanthophoenix nobilis, Nephrosperma Van-Houtteana, Boscheria melanochaetes, Verschaffeltia splendida, and Stevensonia grandifolia. Seven species are native in Mauritius, namely, Latania Commersonii,* L. Loddigesii, Hyophorbe indica,* H. amaricaulis, Dictyosperma album,* Acanthophoenix rubra,* and A. crinita.* The five starred species are also reported from Bourbon, and are the only ones in the island. Rodriguez possesses three species, Latania Verschaffeltii and Hyophorbe Verschaffeltii, both endemic, and Dictyosperma album, which is also common to Mauritius and Bourbon. The Coconut Palm is omitted, as it is not indigenous. Dr. HEMSLEY also describes a number of new Seychelles and Aldabra plants in the *Journal of Botany* for 1916 and 1917. Among these are species of Parinarium, Weihea, Begonia, Jasminum, Northea, Vitex and Dioscorea.

FIG. 105.—APPLE MONARCH: A NEW LATE CULINARY VARIETY.

War Item. M. ALBERT MAUMENÉ, late Editor of *La Vie à la Campagne*, was seriously wounded in the early days of the war. We learn from a French friend that M. MAUMENE'S services are being utilised by the Ministry of Agriculture.

Bounty for the Australian Evaporated Apple Industry. *The Board of Trade Journal* announces that an Act has been passed by the Commonwealth Parliament to provide the sum of £12,000 for the payment of a bounty upon the export of Apples grown and evaporated in Australia and sold to the Imperial Government. The bounty is to be paid to the growers, subject to compliance with awards determining what are fair and reasonable wages and conditions in the growing and the evaporating of Apples. In introducing the measure, the Minister for Trade and Customs stated that for several years the export of Apples to oversea markets totalled from 1,000,000 to 1,250,000 bushels yearly, but owing to the lack of shipping facilities there could be no export in 1918, hence the position of the growers was very difficult. As the price was too low to allow the industry to be carried on, the Government decided to give a bounty of 10 per cent. on the basis value of 7d. per pound, at which 1,800 tons of evaporated Apples were sold to the Imperial Government. Fifty pounds of Apples yield only about six pounds of evaporated Apples, and care would be taken that the bounty would be paid only to the growers. It is claimed that notwithstanding the bonus it does not pay the producers to grow fruit for evaporation at the price offered. The bonus will be paid chiefly to Tasmanian growers, as the bulk of the evaporated Apples for export will be produced in that State. The industry of evaporating Apples to any considerable extent has been quite a recent development in Australia, chiefly in Tasmania. The process follows closely that in operation in North America, and a portion of the equipment for new plant was procured in New York. Two of the most prominent evaporators in Tasmania are visiting Canada and the United States for the purpose of obtaining knowledge of any improved methods in connection with the drying of fruits and vegetables.

THE FLOWER GARDEN.

THE REPLANTING OF FLOWER BORDERS.

A CORRESPONDENT has asked us to advise him how best to replant two flower borders, each 40 feet by 9 feet. These borders slope down to a tennis court which is about 2 feet below the general level of the garden; the soil is light. Very many of our readers have devoted their flower borders to vegetable production during the past four years, but in view of happier times in the near future they will be considering schemes of planting whereby such borders may be rendered

beautiful again; to them, as well as the correspondent referred to, the following reply may prove both suggestive and helpful.

Our correspondent's query seems to indicate that the borders have a rather sharp slope; if such is the case it would be advisable to make a retaining edge of stones, or, if these are not suitable, an edging composed of one species or variety of plant would be advisable, and there is a large choice of plants suitable for this purpose. Any of the following subjects may be used with excellent results. Pinks in variety make a charming edging, their glaucous foliage giving a furnished appearance to the front of the border at all seasons; one variety, such as Mrs. Sinkins, could be used, or, better still, if it can be obtained, the old White Fringed Pink. Saxifraga umbrosa (London Pride) makes a useful edging, as it will grow anywhere and is very charming when in flower, as also is the common Thrift and its white variety—Armeria maritima and var. alba. Santolina Chamaecyparissus (Lavender Cotton) makes a capital edging, and may be kept in shape by clipping; its silvery-grey foliage provides an excellent foil to bright flowering plants in the border. Iberis sempervirens is also suitable for a good permanent edging, and gives a mass of white flowers during April and May. Dwarf Lavender makes a charming and fragrant edging. Cerastium tomentosum, with silvery-grey foliage and masses of white flowers, is also excellent for this purpose, and Nepeta Mussinii is another charming subject for an edging. If it is necessary to use stones to provide a retaining edging then a wide choice of planting material can be found among subjects usually grown in the front line of a herbaceous border.

As the border is empty the opportunity should now be taken to prepare it well by manuring and deep digging or trenching.

In the following selection of plants it is taken for granted that good groups of each sort will be planted, in preference to single plants repeated at intervals. In the absence of a plan it may also be taken for granted that there will be, roughly, three lines of plants, or, more correctly, three lines of groups in the border; this would ensure each group being some 3 feet in depth and passing into the others in an irregular fashion. Some of the second line groups would come well to the front of the border, and the back groups would in part come into the middle groups, and thus break up the lines of the border.

For the first or front line of groups Cerastium tomentosum, Nepeta Mussinii, Iberis sempervirens, Campanula carpatica, Pink Mrs. Sinkins, Aubrietia var. De Mules or Lavender, Gypsophila repens, Heuchera Zabeliana, Campanula carpatica var. alba, Alyssum saxatile, Crucianella stylosa, Thalictrum adiantifolium, Phlox Newry Seedling, and Sedum spectabile will serve.

For the second line of groups a good selection would be Phlox Frau A. Buchner, or Mrs. Jenkins, Silvia virgata, Chrysanthemum maximum var. Mrs. C. Lowthian Bell, Paeony Reine des Roses and P. albiflora, Iris pallida var. dalmatica, Anemone japonica var. Whirlwind (white) and var. Queen Charlotte (rose), Erigeron Quakeress, Phlox Elizabeth Campbell, Eryngium planum, Campanula persicifolia var. Moerheimii, Helenium pumilum var. magnificum, Gypsophila paniculata var. flore-pleno, Sidalcea Listeri, Pyrethrums James Kelway and Queen of the Whites, and Veronica subsessilis.

The third, or back line of groups should consist of taller subjects, such as Aster Robert Parker, Delphiniums—seedlings or named vars. such as Duke of Connaught (bright blue), or Persimmon (light blue), Lathyrus latifolius var. White Pearl, Verbascum Chaixii, Echinops nivens, Aster cordifolius elegans, Achillea Eupatorium, Hollyhocks, mixed, single or double; Thalictrum aquilegifolium, Mulgedium (Lactuca), Bourgaei, Lupinus polyphyllus (blue and white), and Kniphofia Lachesis.

The planting scheme for the second border may differ from the first, and include the following plants in the front line of groups: Statice latifolia, Arabis albida var. fl. pl., Gaillardias, Pinks, Geum Mrs. Bradshaw, Achillea Ptarmica var. The Pearl, Potentilla Gibson's Scarlet, Stachys lanata, Pentstemon barbatus, Chrysanthemum Parthenium var. fl. pl., Aster Linosyris, Heuchera sanguinea, Geranium sanguineum, Saponaria officinalis alba fl. pl., Oenothera Youngii, Polemonium coeruleum and its var. album.

For the middle or second line of groups we advise Dictamnus albus, Anchusa italica var. Dropmore, Sidalcea candida, Phlox Etna, Lychnis chalcedonica, Kniphofia Saundersii, Galega officinalis var. alba, Verbascum densiflorum, Inula glandulosa, Thalictrum glaucum, Aster ericoides, Morina longifolia, Malva moschata var. alba, Poterium obtusatum, Papaver Jenny Mawson, Hemerocallis flava and Aster acris, while for the back or third line of groups suitable subjects are Acanthus mollis, Cephalaria alpina, Aster Beauty of Colwall, Bupthalmum cordifolium, Delphiniums, Aster Chastity, Hollyhocks, Helenium Riverton Gem, Bocconia cordata, Aconitum Wilsonii, Chrysanthemum uliginosum, Aster rubra, Helianthus rigidus var. Miss Mellish, Delphiniums, Eupatorium purpureum and Spiraea Aruncus.

The selections given above may appear rather restricted in variety, but, as the soil is described as sandy, some subjects liable to suffer from drought have been omitted. Further, the personal taste of the planter must decide whether or not there should be greater variety and smaller individual groups.

Many hardy spring-flowering bulbs may be planted between the groups of herbaceous plants. As their foliage dies down Wallflowers, Myosotis and other spring-flowering subjects will serve to brighten the bare spaces. Biennials, such as Sweet Williams, Canterbury Bells, and Coreopsis grandiflora, may be used to fill spaces between other plants. Pentstemons are very useful in this connection, especially the varieties Southgate Gem and Crimson Gem, while East Lothian Stocks and Antirrhinums in many fine varieties are also very useful, and both can be raised in heat early in the year.

Some of the best hardy annuals prove useful for maintaining a continuous display. Mignonette should be sown wherever there are likely to be any bare patches. Sweet Alyssum, Bartonia aurea, Coreopsis, Candytufts, Chrysanthemum carinatum vars., Clarkias, Eschscholzias, Godetias, Larkspurs, Lavatera trimestris, Lupinus nanus and L. Hartwegii; Malope grandiflora in crimson, rose and white forms, Nigella hispanica, Portulacas, and Platystemon californica, are all useful annuals, and most of them have a long flowering season.

ON INCREASED FOOD PRODUCTION.

TOO MUCH-ALIKE POTATOS

In my early days our people grew something like a dozen varieties of Potatos, all of which I could readily identify or recognise by the characters of the stems and foliage, while the tubers were all very distinct and easy to determine. I could recognise them on other farms and readily detect something different. The groups of similar varieties mentioned by *E. J. Collins* (p. 226) reminds me that I have a list of thirty of the Up-to-Date type, fourteen almost or quite indistinguishable from Abundance, six of the Beauty of Hebron type, five like Great Scot, three like The Lochar, and three like Mr. Bresee. The chief difficulty of these much-alike varieties is the impossibility of separating the tubers when they get mixed. The opportunities for mixing them are many, without implying carelessness. If several of them are grown in one field it is quite impossible to prevent mixing them, if lifted with a plough or Potato-digger.

This mixing would not much matter, apparently, if all the varieties were similar in character, quality, and productiveness, but some might be of recent origin, vigorous and disease-resisting, while some might be immune to wart disease and others not. In these latter cases mixing would be a decided evil, especially in districts where black scab prevails. Dominion has tubers similar to Up-to-Date, but is immune to wart disease, and this is a decided difference, for I know of no others of the group that possess that quality.

All the Potatos of my early acquaintance flowered freely, except the second-early, Glenberrie Early, which invariably dropped its flowers in bud. A large proportion of them produced berries in the open fields. Now these two features have largely disappeared. According to my observations, freedom of flowering is largely a question of climate, soil and surroundings. Flowers are far more prone to drop in bud in gardens and warm, sheltered areas than in good soil in exposed fields. The dropping of the flowers, the growing lack of pollen, and the similarity of many varieties, both in tubers, foliage, stems and flowers, seem to me to be evidence of too much in-breeding in order to secure productiveness, as well as white-skinned and white-fleshed tubers. Having regard to the future, and the raising of new varieties, it would be well to use parents of more distant affinity, and not overlook the advantage of pollen-bearing varieties as parents. *J. F.*

POTATO MAJESTIC.

THE remarks of Mr. John Robertson, on p. 235, bear out what I have experienced and heard of from hundreds—the wonderful cropping power of this new Potato. Your correspondent states that the seed supplied to him was "as grown," and by no means a good sample. if the tubers had all been of proper seed size the quantity purchased would have planted a wider area, with a correspondingly greater yield." That was true last year, and I fear it will be true to a great extent this coming planting season. I wonder if Mr. Robertson had many seed-sized tubers in his crop? It is quite the exception to get many. Last week I spent some hours with a friend who grew about 100 acres of Majestic, but I could not persuade him to sell me any dressed through a 2½-inch riddle. "No," Mr. Cuthbertson," he said, "but you can have as many as you want 'as grown.'" Let me relate an experience my firm had the other day. A farmer who grew several acres of Majestic, and whose crop we had inspected several times, undertook to deliver tubers dressed through 2½ and over 1¾ inch mesh. He did this at a price exceeding £30 a ton, and out of each ton, before that lot was fit to sell in small quantities, had to be taken 5 cwt. per ton! A few tubers were too big, a number were bruised, and many unshapely. It is, however, not a bad feature of a new Potato that it gives plenty of big tubers. One of our best-known growers and merchants in the south of Scotland simply stood aghast as his crop was being turned out—it was nearly all lumpers together. There is a great interest in and an excellent demand for Majestic. Unfortunately in some districts cut seed did not do well last season, and it would be doing a public service if your readers would write of their experience with cut seed. In East Lothian many acres were almost total failures where seed had been cut. After planting, dry weather set in, and the cut sets did not grow. My own experience was that 5 to 10 per cent. of the cut sets failed, not more. My advice is to sprout the sets about half an inch before cutting; cut carefully, and not into too small pieces, a few days before planting, and dust the cut surfaces with powdered lime. *W. Cuthbertson, Duddingston, Mid Lothian.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Flowers in Season.—We gathered our first blooms of Iris stylosa on December 5. Erica lusitanica, E. carnea, E. c. alba, and E. mediterranea hybrida are in flower, and Rhododendron praecox is showing colour. We have had a fine lot of late Roses, especially Zepherine Drouhin, which is now a lovely colour. This variety has a beautiful scent, and it is thornless. The Diplopappus is in flower, and is always charming for its foliage alone. Primroses and Daisies and Violas are flowering freely. I have never seen Jasminum nudiflorum better in flower; no recently introduced plant is its equal as a winter-flowering subject. Chimonanthus fragrans is flowering, and we have collected a good lot of seed this season. Many Rhododendrons are well advanced in bud, too far, I am afraid, to withstand frost. Raspberries are fruiting well and freely, and I have gathered several good dishes of the berries quite recently. *W. A. Cook, Abbots Wood Gardens, Guildford, Dec. 17.*

Wireworm.—The references to wireworm by Mr. McGlashan and Mr. Molyneux on pp. 235 and 243 induce me to relate a remark which I heard made this spring, with a view to combating the pest. It was to roll the land at night with a heavy roller, but rolling would not be effective if done during the day. I give the observation to what it may be worth, and what rolling seems to cut the question extra large area, it might be tried on a small scale to see if there is any truth in the statement. *E. B. Fotu.*

Silver Leaf Disease. Writers on Silver Leaf disease almost without exception display weakness in their suggested remedies to combat the disease by simply saying "burn the trees!" Destroying affected trees is but a poor solution of the difficulty. I do not wonder at the suggestion when writers cannot offer any practical remedy. Is this because they have not tested one? "H. H." in his opening paragraph on p. 215, states: "Trees so affected are incurable right." Certainly they are if no practical steps are taken to deal with the fungus and destroying them. This bald statement that the trees once affected are beyond cure I flatly contradict, as I know it is possible to effect a cure in some cases certainly. Later, "H. H." says: "Every tree which develops the silvered foliage of this disease should be looked upon as stricken beyond recovery." This assertion plainly proves to me that H. H. has no practical knowledge of cures. Destroying a tree is not a cure. Has H. H. made any attempt to cure the disease in a tree? I must not believe in the theory that the spores are carried by the wind. I rather hold the opinion that the trouble comes from the roots in the same way that canker affects Apple trees. Mr. Lynch says: "It is true that the spores germinate and attack the trees through a wound." What proof have we of this beyond supposition? Has Mr. Lynch ever detected such wounds, clean at first, watched the reception and progress of the spores in their germination and growth, and seen the result in actual silver leaf affection. Proof is what I am seeking; theorising is weakness to me. I want to hear of some practical remedy that has been tried and of its failure or success. We do not get the slightest testimony of such trials from writers generally. "H. H." does little more than quote what the various leaflets have told us, and these are well known to growers generally. I know quite well it is possible to cure silver leaf disease in Apple trees, but not by cutting down the trees. The rooting conditions must be altered. I fear it is little use looking to scientists and theorists for practical advice on this subject, therefore we must map out our own salvation in this serious affection of fruit trees, which, if allowed to go on, will do much damage, and dishearten planters. *E. Molyneux.*

In reply to Mr. Molyneux and other recent correspondents, might I suggest that perhaps the reason why the Food Production Department does not suggest other curative measures for Silver leaf is that it is unaware at the present time of the existence of any alternative remedy which can be applied on a large scale and be relied upon to give satisfactory results. The measures advocated in the Food Production leaflet have been tried extensively with success, hence their recommendation. It is known that several workers have treated small groups of silvered trees in other ways with apparent success, but whenever these methods have been applied on a large scale the results, so far as I am aware, have been unsatisfactory. It is not often realised that there is probably a natural recovery from this malady of 10 per cent., hence the results of treatment of individual trees are often misleading unless adequate controls are kept. Papers in the *Journal of Agricultural Science* for 1911 and 1913, summarised also in the *Journal of the Board of Agriculture* and in *The Gardeners' Chronicle*, gave an account of my researches on this disease up to that year. Since that time much further work has been done both at Cambridge and in co-operation with Mr. M. A. Bailey, of the John Innes Horticultural Institution, Merton, but the exigencies of the war have unavoidably delayed the publication of the results of these investigations. It is hoped, however, that present conditions will allow of this being done in the near future, and of the work being continued with increased vigour. Our further investigations support the view expressed by me in 1915 that Silver leaf disease is a general pathological condition which may be induced by various causes, by far the most important of which from the economic standpoint is the fungus Stereum purpureum acting as a wound parasite. There is no evidence at present that the disease is due to a soil organism. With regard to the statement of Mr. H. S. Hayward that he has not observed Plums, Cherries and others on their own roots affected by the disease, he may be interested to know that the common Laburnum growing on its own roots is often affected by Silver leaf in private gardens, chiefly because it is usually so severely cut back that the fungus has abundant opportunity to effect an entrance. *E. F. B.*

Rabbits and Fruit Trees. *Market Grower* (p. 230) is doubtful as to the right way to protect young fruit trees from rabbits gnawing the bark. I advise *Market Grower* to give up the practice of using wire netting and use Bentley's Tree Protecting Paint, which he will find saves much expense and labour. The surroundings of an orchard of 7 acres here are fairly well stocked with rabbits. Wire netting was formerly used for protecting the stems, but it always needed attention after rains were turned in the orchard to feed. I was advised to try Bentley's Tree Protecting Paint, which I did with good results. I used it Oct. last this year and as a good substitute for rabbit skins. *C. Dixon, Holy Wells Park, Ipswich.*

The Deliverer of Trees. At this season of the year nurserymen receive many complaints of the delay of parcels of fruit trees on rail, and many fear that such trees if more than a few days out of the ground will suffer. With careful packing this is not so. We heard recently from a customer whose trees were lost on the rail for three months last year, and when they finally reached their destination they were planted, and have thrived well since, showing no ill effect from their long absence from the soil. *George Bunyard and Co., Ltd., Royal Nurseries, Maidstone.*

SOCIETIES.

NATIONAL CHRYSANTHEMUM.

A MEETING of the Executive Committee was held on the 16th inst., at the offices of the British Florists' Federation, Covent Garden. The attendance was good, and Mr. Thos. Bevan presided.

The interim financial statement proved highly satisfactory, and promised a balance in hand at the end of the year, with no liabilities, and a Reserve Fund of £75 still untouched. The sub-committee appointed to draw up lists of desirable early flowering Chrysanthemums reported that considerable progress had been made in reducing the numbers of names of varieties in lists obtained. The Committee agreed the Society should become attached to the Chamber of Horticulture, and that a show should be held on November 4, 1919, in conjunction with the meeting of the Royal Horticultural Society fixed for that date. Provisional arrangements were made for Floral and Executive Committee meetings in the coming year, and the annual meeting will be held as usual on the first Monday in February.

An interesting discussion took place concerning the future work of the Society, and proposals to hold general meetings, with lectures, after the business meetings of the Committee, and to arrange for a scheme of lectures for affiliated societies, were favourably considered.

CROPS AND STOCK ON THE HOME FARM.

EELWORM IN CORN.

IN the October number of *The Journal of the Board of Agriculture* Professor Somerville has an interesting and enlightening article on "Ear Cockles in Wheat," with illustrations of an ear of Wheat, showing the cockles, which are the foundation of stem-eelworm, and so detrimental to a crop, not only of Wheat, but more especially of Oats.

Amongst farmers ear cockles are known as burnt Corn, and are considered by some to be harmless. No doubt this trouble is widely distributed; probably it is most serious in the south and south-west of England. In Hampshire it is very troublesome in some seasons, and is more marked in Oats than in Wheat, for the reason that Oats usually follow Wheat.

The cockles or seed of the eelworm are originally produced by the Wheat crop. The affected ears shed their false Wheat grains at harvest time; they lie in the soil, and develop the following year in the Oat crop. It is safe to assume that the whole cause of the attack is through sowing seed containing ear cockles, generally introduced in Wheat. From experiments carried out with affected ears of nursery Wheat sown in pots Professor Somerville gives some startling results. In one instance one cockle was sown in the centre of the pot, and although there were not so many ears attacked, nor so many cockles produced as where more cockles were sown, infestation was sufficiently pronounced to indicate the damage that may be done to a field of Corn even if the number of cockles in the seed grain is a comparatively small one.

It is found that the eelworms liberated from the single cockle had considerable power in moving through the soil, as was evident from the fact that the outside plants in the pots were almost as badly attacked as the plants growing in the centre. Professor Somerville deserves the thanks of all farmers for drawing attention to this subject.

Some farmers are not nearly so careful as they should be in selecting their seed Wheat; too many make the mistake of sowing the seed direct from the threshing machine, which cannot be expected to take out such impurities as cockles, for example.

Clover sickness, too, may easily be pronounced owing to the presence of eelworms in the soil, therefore this is another reason why farmers should be more careful with seed grain, as Clover often follows Wheat.

For the eradication of eelworm in soil Strawson's "Vaporite" should be a valuable aid. I hope to give this preparation a thorough trial in the coming season, especially for an Oat crop following Wheat affected with eelworm if the seed was imported. I hear wonderful accounts of the value of "Vaporite" on market garden crops, how it enables cultivators to grow almost any crop, and especially Swedes, that formerly would not succeed on a particular soil.

For agricultural crops cereals especially, the makers advise 2 cwt. per acre, to be evenly distributed over the land and ploughed in, which is better than harrowing it in from surface sowing. The point is, to have the "Vaporite" thoroughly mixed with the soil, seven days at least before the seed is sown.

CHEMISTRY OF THE SOIL.

What a lack of knowledge there is among cultivators, and not only among farmers but horticulturists, too, in the determination of the deficiencies or excesses of certain constituents

in the soil! To those who are almost entirely dependent upon artificial fertilisers for increasing the productiveness of their land a knowledge of how to determine what is lacking in their particular soil would be of very great value. From recent utterances we are led to believe that much assistance is to be given to cultivators of the soil in some form or other in the near future, and I suggest that help in this direction would be one popular way of rendering assistance, either in disseminating knowledge or in cheapening fees for analyses of the soil. Even better would it be to set up in each county a centre where soil would be analysed free of charge.

SMALL HOLDINGS.

In election speeches all sorts of suggestions have been made about small holdings, and that they should be encouraged I most heartily agree. A Labour candidate recently gave me a shock by saying, "Small holdings have been a failure, because the men know nothing of the business. The thing to do is to get a Government that will use the land for the people, then set up colleges to give the people an opportunity to learn the business of cultivating the land." My experience of small holders does not coincide with this statement from a town-dweller. There is no more deserving person than an up-to-date small holder. What he sincerely desires is improved transport facilities whereby he can convey his produce more promptly to the market or shop, as the case may be. There are many amateurs, cottagers and allotment holders who would produce much more food for the people if they had better means of transport. His second point is greater security of tenure and full compensation on quitting. Few persons realise the labour a practical small holder or allotment cultivator spends on such details as trenching the soil, not to mention the large amount of manure he applies, as an absolute necessity to obtain the best results. To be discharged from such a holding at short notice does not seem right.

POULTRY.

With the more liberal release of "tail" Corn and an extension of food generally, poultry keepers are looking hopefully to the near future when the industry will shortly become nearer its normal pre-war condition.

The months of October and November are proverbially the most troublesome of the whole year for egg production. The pullets in December, when carefully timed to hatch at the right period, give eggs when most needed, and with the added food they will continue to lay. During the autumn and winter the semi-intensive system of poultry-keeping is infinitely the best. A careful person will produce more eggs from ten birds under this method than another will with three times the number under the ordinary farmyard conditions, which all too often means allowing them to roost in none too clean a building, and letting them out early in the morning with a view to finding the bulk of their food no matter what the weather is. The fowls, in such conditions, find their way to the nearest shelter from wind, cold or rain, where they remain, "humped up," for the bulk of the day, or so long as unfavourable conditions continue.

On the semi-intensive plan, a warm, clean house is provided, with plenty of exercise in the scratching material, such as chaff, dry leaves, or caving, amongst which the Corn is fed. To obtain their food the birds have to seek it by scratching, and thus keep themselves warm. During wet weather they are not let out in the open, but kept warm and dry. Liberal feeding of poultry under the various conditions is the correct method, no doubt, but excessive feeding is unwise at any time. Turkeys, cockerels, ducks or geese intended for killing should be restricted in their opportunity for exercise; indeed, they are all the better if shut up entirely, and fed on soft food such as Oatmeal and milk, when obtainable.

PITTING SWEDES.

Where Swedes are grown for the use of ewes and lambs in March and April it is a good plan to preserve them from probable injury by frost by "pitting" them during December in the field where they were grown. Not only does this method of storing the roots protect them from frost, but it maintains their feeding value, which they lose when allowed to remain standing and when making new growth toward seeding in spring. By this action the roots become hard and "woody," and of much less value from a feeding point of view. The method of "pitting" consists of pulling up the Swedes, putting them into heaps—with the roots, tops and soil them into heaps—with the roots, tops and soil intact—of about 6 bushels, and covering them intact—of about 6 inches of soil, which will ward off much frost; by this covering air is largely excluded, thus checking the tendency to growth. When required by the sheep, the soil is put back into its place and the roots spread out thinly some days before the sheep reach them, to enable the blanched tops to wilt, which renders them less likely to scour the lambs.

PIGS.

During the months of December and January, which are not ideal periods for the birth of young pigs, greater attention is necessary to the sows and their young than two months later, when the weather is warmer. All breeding sties should be kept warm, free from draughts, and in a place with a southern exposure, so that the newly born pigs may have the advantage of sun, which they revel in even when but two days old. A close, wooden floor with a gentle slope is an advantage over one of brick, cement, or even earth, being warmer, and preventive to a great extent of cramp in the young pigs, which is all too common when cement floors are used. After birth of the young the sows should be carefully, and, as time goes on, liberally fed with milk and meal. The young pigs, too, should be quickly encouraged to drink milk in a separate trough in an adjoining stye where they are apart from the sow, who seems to think all the food is for herself only. My plan is to have a temporary hole through the partition of one stye to the next, through which the small pigs soon find their way. *E. Molyneux*

TRADE NOTE.

MESSRS. HURST AND SON'S 75TH ANNIVERSARY.

AT the invitation of Mr. Edward and Mr. William Sherwood, the staff of Messrs. Hurst and Son, Houndsditch, dined at the Holborn Restaurant on the 18th inst. Mr. Edward Sherwood presided, and was supported by his brother and sister (Mrs. Campbell), Sir Thos. Mackenzie, High Commissioner for New Zealand, Mr. W. Atkinson, Mr. G. Townsend, Mr. G. J. Ingram, Mr. H. Morgan Veitch, Mr. Geo. Monro, jnr., Mr. Chambers, of the Seed Section of the Food Production Department, Mr. B. Wynne, Mr. C. E. Pearson, Mr. C. H. Curtis, Mr. Macselfe, and Mr. May were among the visitors. The departmental managers acted as vice-chairmen at the several long tables. Altogether the company numbered about 190, including many women workers.

After the loyal toasts had been duly honoured, Sir Thos. Mackenzie proposed "Continued Success to the Firm," and in doing so referred to the sympathy that had always existed between the employers and employed at Messrs. Hurst and Son's establishment; to the high esteem in which Mr. Edward Sherwood's ability and experience were held by Government Departments; to the fifty men who had donned khaki, several of whom had made the supreme sacrifice; and to the need for using the raw materials produced within the Empire for the Empire's needs, so that the Germans would never again be in the position to bid for world power. Mr. Edward Sherwood, in responding, expressed the pleasure he felt at seeing so many members of the staff and so many visitors present, and said all had worked hard and done their best during four and a-half difficult years. On occasion, as when they had to send a big consignment of seeds to Serbia, and when they had to send 250 tons of seeds to the Balkan Peninsula, they had to work hard, and at great speed, but no one had slacked. The past 25 years has been a time of steady progress for the firm, and he hoped that 25 years hence all would be present at a similar friendly gathering.

Mr T. N. Cox proposed "The Visitors," to which Mr. W. Atkinson and Mr. G. Townsend responded, and each referred to the proud position Messrs. Hurst and Son deservedly hold in the seed trade throughout the world. Mr. Carey Tucker proposed "The Ladies," and a lady member of the staff, Miss Bardwell, responded most ably. "The Staff," proposed by the Chairman, gave Mr. Sherwood his opportunity of referring to work loyally accomplished, and the way women had taken the place of the absent men. He also stated that this occasion was really the celebration of the firm's 75th anniversary. Messrs. D. Bryant, F. W. Locke, and J. E. Dixon replied, and each emphasised the point that there would be little industrial unrest if employers generally treated their employees as Messrs. Hurst and Son did.

The toast of "The Chairman," accorded with musical honours, was proposed by Mr. S. N. Sampson, who expressed the generally felt hope that Mr. Sherwood would preside 25 years hence, when the firm celebrated its centenary. Mr. Sherwood, in rising to respond, received quite an ovation. He returned thanks for the good wishes extended to him and his brother and sister, and said it was the intention of the firm to revive the annual outing and holiday for the staff, at Kelvedon, in the coming year.

A very full musical programme was provided, and the whole proceedings were most enjoyable.

ENQUIRY.

FUMIGATING PAPER.

WILL any reader inform me where I can procure Appleby's Tobacco Paper for fumigating purposes? *J. R. B.*

ANSWERS TO CORRESPONDENTS.

NAMES OF FRUITS: *R. A. P.* 1, King of Tompkin's County; 2, King of the Pippins; 3, Braun'ey's Seedling.—*P. T. W.* 1, Beurré Chairgeau; 2, Catillac; 3, not recognised.—*S. C.* 1, Adams's Pearmain; 2, Ribston Pippin; 3, probably Dutch Mignonne; 4, King Harry.—*E. C. S.* 1, Calville St. Sauveur; 2, Golden Russett.—*M. T. G.* Hanwell Souring.—*H. B.* Lane's Prince Albert.—*B. B. T.* Beurré d'Anjou.—*J. O.* Cellini.

SOIL FLOODED BY RAIN AND SEA WATER: *J. H.* The soil, as represented by the samples sent, is in a very inert and unfertile condition. Thorough drainage is essential, and means should be taken to prevent flooding by sea water. Floods of sea water are very detrimental to soil in which garden crops are cultivated. The soil lacks fibre, and is deficient in lime. After the land has been drained it should be deeply cultivated, old manure and charred garden refuse being added as the work proceeds, with some basic slag. In the spring, about three weeks before sowing or planting, apply about 1 lb. of air-slaked lime to the square yard, and lightly fork it in. If manure is not available now, apply the lime at once, ridge up the soil as roughly as possible, and add well-decayed manure later in the winter. The presence of so many dead worms was due to the flooding, particularly to the sea water.

SCALE ON PEACH TREES: *G. B.* Caustic alkali would be a dangerous specific to use for the destruction of scale insects on Peach trees under glass, and cannot be recommended. Both flower and wood buds are extremely delicate, and their protective covering is easily penetrated, being of an absorbent nature. A safe and efficient remedy is Gishurst Compound, used at the prescribed winter strength, and at a temperature of 100° to 110° Far., after having first syringed the trees with hot water at least 10° warmer. The best method of using this specific is to apply it with a new paint brush, stroking each shoot upwards only. If this is done thoroughly it should be effective in destroying the scale insects.
